Mapping a functional viral protein in solution using synchrotron X-ray footprinting technology. *Synchrotron Radiation News* 18(1): 25-34 (January/February, 2005). Cover: Synchrotron Protein Footprinting: the study of protein structure and dynamics in solution using synchrotron X-ray radiolysis. The intense X-ray from the synchrotron radiation generates hydroxyl radicals, which react with the surface accessible side chains of the adenovirus proteinase seen in space-fill mode (on the left). Proteinase digestion followed by chromatography and mass spectroscopy is used to identify the extent and sites of oxidation. The binding of cofactors, pVlc and DNA to the protein protects specific residues from attack. Using this data, a model of DNA binding to AVP is developed that provides a molecular mechanism for cofactors dependent activation (on the right). (See article on page 25.)
