Negative staining and cryo-EM sample preparation

Liguo Wang

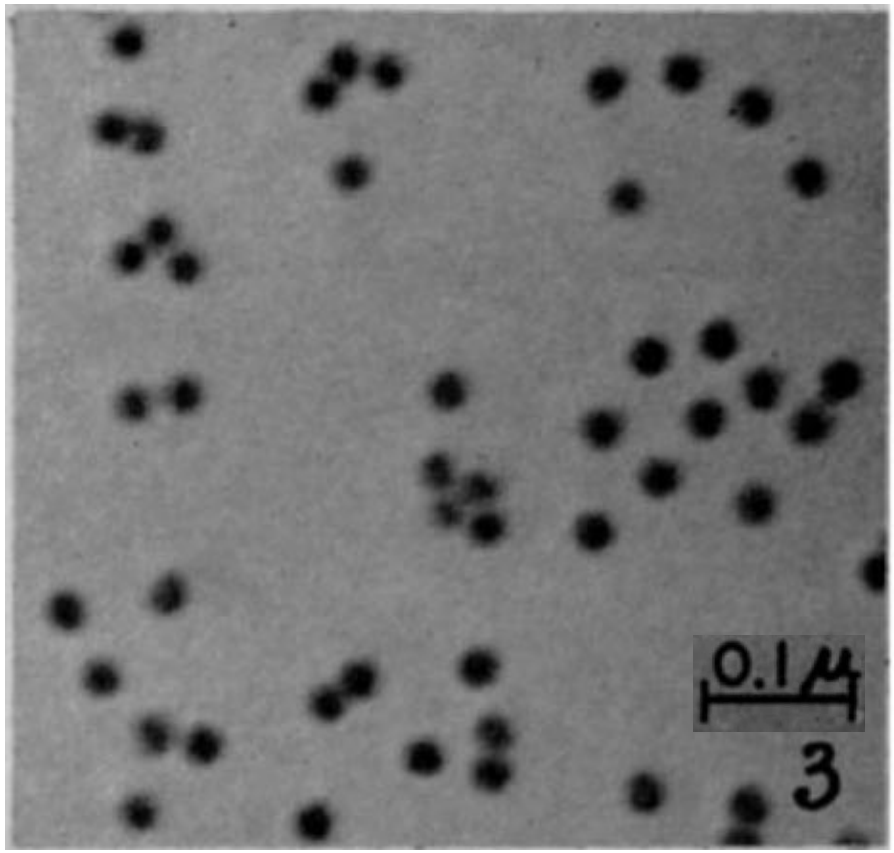
LBMS, BNL

Negative staining

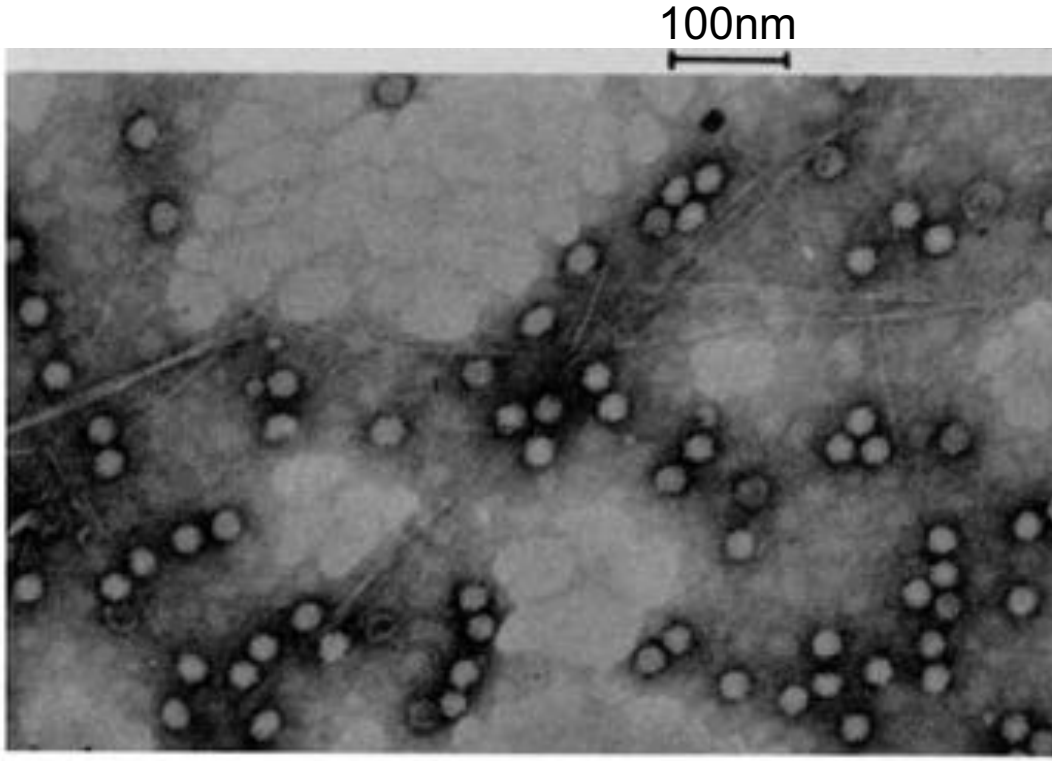
EM requires a vacuum - an environmental constraint that is incompatible with unprotected biological material.

To enhance visualization of biological samples

BSV stained with 1% 12 PTA
（Phosphotungstic acid）pH 0.7



BSV stained very lightly with 5% PTA
at pH 4.6 and insufficiently washed

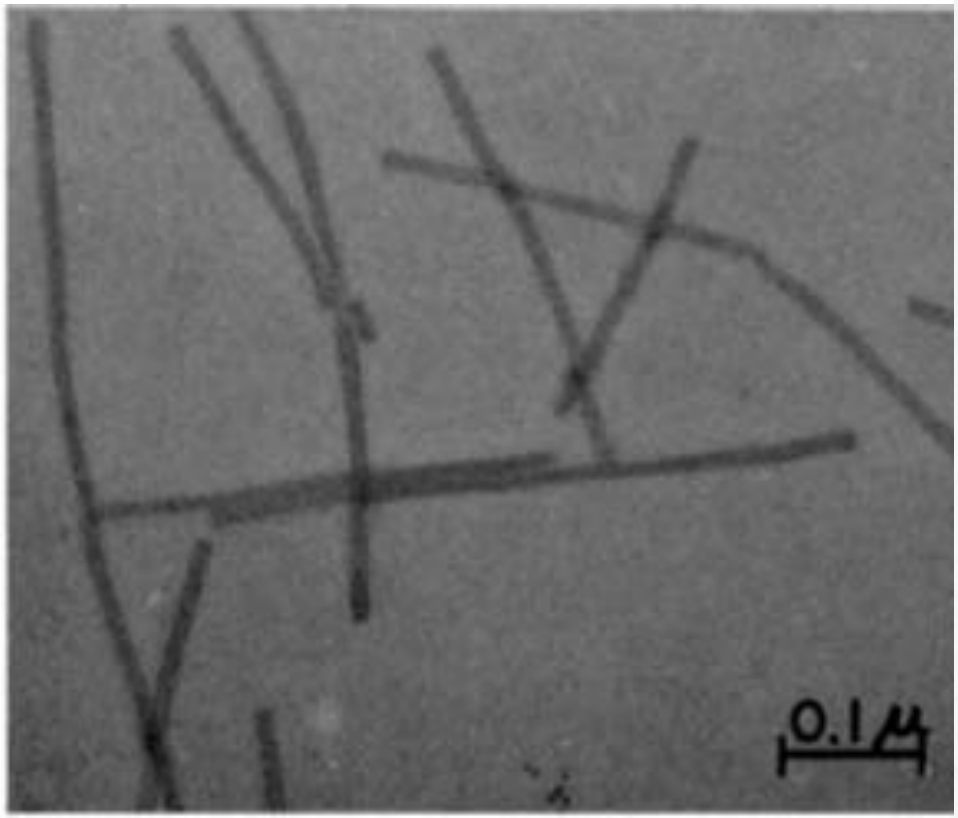


In the pH range above 2 where the tomato bushy stunt (BSV) viruses are stable, the amount of stain absorbed is too small to produce adequate contrast in the electron microscope. Maximum stain absorption was achieved at pH about 1.

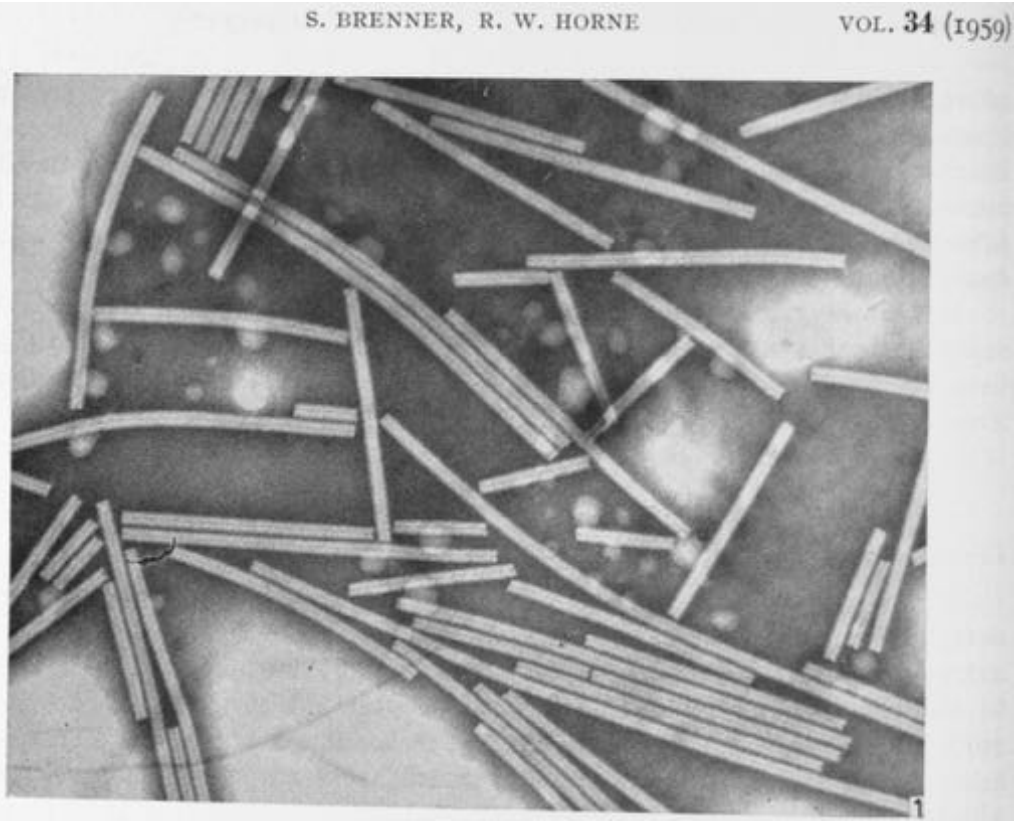
Hall, C. E. (1955). The Journal of Biophysical and Biochemical Cytology, 1(1), 1-12.

Negative staining

Phosphotungstic acid
(40% pH1.0, well washed)



Phosphotungstic acid
(2% pH7.4)



Tobacco mosaic virus (TMV)

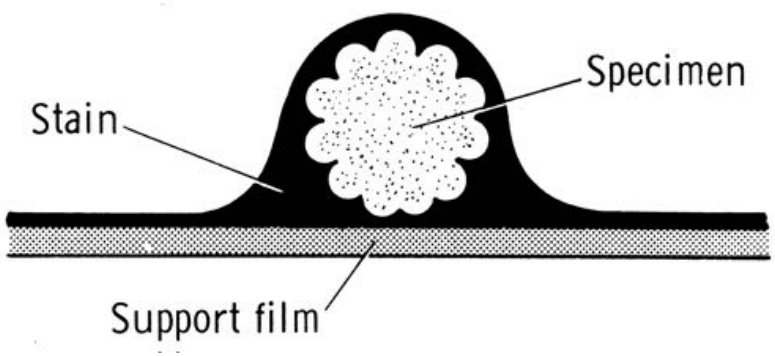
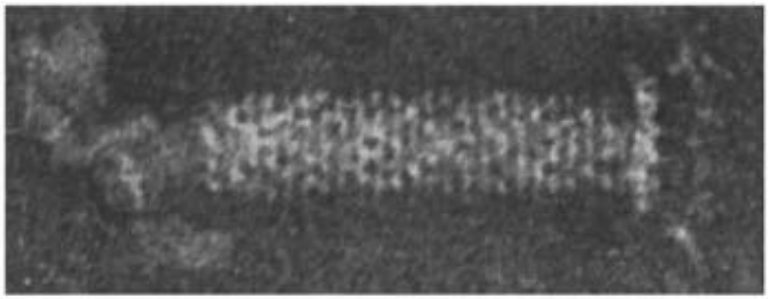
Brenner, S. & Horne, R. W. (1959). Biochimica et Biophysica Acta, 34, 103.

Negative staining

EM requires a vacuum - an environmental constraint that is incompatible with unprotected biological material.
To enhance visualization of biological samples

Negative staining exploits that salts of heavy metals are relatively insensitive towards electrons and form **a stable "cast" around the molecules** when dried down. Salts such as uranyl acetate or phosphotungstic acid titrated to neutral pH, vanadates and molybdates have and are still being used.





- Sample appears "white" and the electron-dense stain is "black".
- Helps to reduce dehydration and radiation damage effects.
- Attainable resolution is ~ 15-25 Å.

Hydrophobicity of supporting films

γ_L = surface tension of the liquid

γ_S = surface tension of the solid

γ_{SL} = interfacial tension between the liquid and solid

θ = wetting angle

At equilibrium: $\gamma_S = \gamma_L \cos\theta + \gamma_{SL}$

Perfect wetting conditions occur when $\theta = 0$

Glow discharge to change surface hydrophobicity

Applying a potential difference (of a few 100 V to a few kV) between two electrodes. Electrons that are emitted from the cathode are accelerated away from the cathode and give rise to collisions with the gas atoms or molecules in a chamber (a few mTorr to 1atm). The collisions give rise to excited species, which can decay to lower levels by the emission of light. This process makes that a gas discharge plasma typically emits a characteristic glow (and is therefore also called “glow” discharge).

Pelco Easiglow Glow Discharge Cleaning System

Glow discharge to change surface hydrophobicity

Atmosphere	Surface Condition	Charge
Air	Hydrophilic	Negative
Air (with subsequent magnesium Acetate treatment)	Hydrophilic	Positive
Amylamine (Pentylamine)	Hydrophobic	Positive
Methanol	Hydrophobic	Negative

*Dubochet, J., Groom, M. and Mueller-Neuteboom, S. (1982), Mounting of macromolecules for electron microscopy with particular reference to surface phenomena and treatment of support films by glow discharge. Advances in optical and electron microscopy, Barrer, R. and Cosslett, V. E. (eds.), Academic Press, London, New York. 107-135.

Glow discharge to change surface hydrophobicity

"Concerning the hydrophilic/hydrophobic nature of the amyl-amine (pentylamine) glow-discharged film, we had the following observation. Simple tests for the hydrophobiciy/hydrophilicy of a grid consist in
- touching the edge of the dry grid with a drop of water. If the surface is very hydrophilic, the drop spread immediately over the whole surface.
- touching the edge of the grid covered with a drop of water with a blotting paper. If the surface is very hydrophilic the water goes in the blotting paper but a thin layer of water always remains on the whole grid.

The strange thing with amyl-amine treated film (as I was used to do it) is that the film was hydrophobic according to the first test but hydrophilic according the second test, once the drop was forced on the surface. We proposed some explanations but they have never been seriously tested as far as I know. Complicated!"

Jacques Dubochet, Feb 12, 2009

Staining solutions

Stain	Density (g/ml)	Useful pH range	Radiation sensitivity	Contrast	References	Comments
Uranyl acetate	2.89	3– 4	Moderate	High	Van Bruggen et al. [101]	Fixative effect
Uranyl oxalate	2.50–3.07 [b]	3– 7	Moderate	High	Haschemeyer and Meyers [10]; Mellema et al. [102]	Very light sensitive, store frozen
Uranyl nitrate	2.81	3– 4	Low	High		
Uranyl formate	3.70	3– 4	Moderate	High	Haschemeyer and Meyers [10]; Leberman et al. [103]	Fixative effect, smallest grain size
Uranyl sulfate	3.28	3– 4	Low	High	Estis et al. [104]	Reported not to recrystallize upon irradiation with electrons
Na/K-phosphotungstate	1.69 [c]	4– 9	Low	High	Brenner and Horne [105]	Positive staining, increases with lowering the pH; destructive effect on phospholipid membranes
Na silicotungstate	2.84 [d]	4– 8	High	High	Sherman et al. [106], Terry [107] Haschemeyer [108]	
Methyl-phosphotungstate		4– 9.5	Low	Medium	Oliver [109]	
Methylamine tungstate	3.88	3–10	Low	High	Faberge and Oliver [110], Shaw and Hills [111]	Supposed not to be a positive stain at any pH. With glycoproteins, add tannic acid
Ammonium molybdate	2.28	5– 8	Moderate	Medium	Bohonek [112], Manella and Frank and [113]	Good for membranes, some fibrous proteins
Aurothioglucose	2.92	4–10	High	Low	Kühlbrandt [114], Kühlbrandt and Unwin [13]	Yields Au-crystallites upon electron irradiation
Cadmiumthio-glycerol	2.0	4–10	Moderate	Low	Jakubowski et al. [15]	No crystallite formation upon electron irradiation, possibly useful with undecagold
Vanadate	2.85 [e]		Low	Low		Very light stain, can be used with undeca-gold labelling

Bremer, A. et al Ultramicroscopy 46 (1992) 85-111

Staining solutions

Stain	pH range	Note
Sodium (K) phosphotungstate	5-8	Significant disruptive effect on many membrane systems. Interact with lipoproteins. Less likely to precipitate with salts and biological media
Uranyl acetate (1-3%)	4.2 – 4.5	Highest electron density and image contrast
Sodium silicotungstate (1-5%)	5-8	Good contrast; Good for small particles and individual molecules
Ammonium molybdate (1-2%)	5–7	Best results for many types of specimen; Lower electron density than other stains
Methylamine tungstate (2%)	6-7	Contrast is not as good as uranyl acetate. Resolution is good.
Uranyl formate (0.75-1%)	4.2-4.5	Best for small molecules, but only stable for 1-2 days.
Nano-W® (methylamine tungstate)	6.8	excellent spreading qualities and a high density for high contrast

Radiation damage

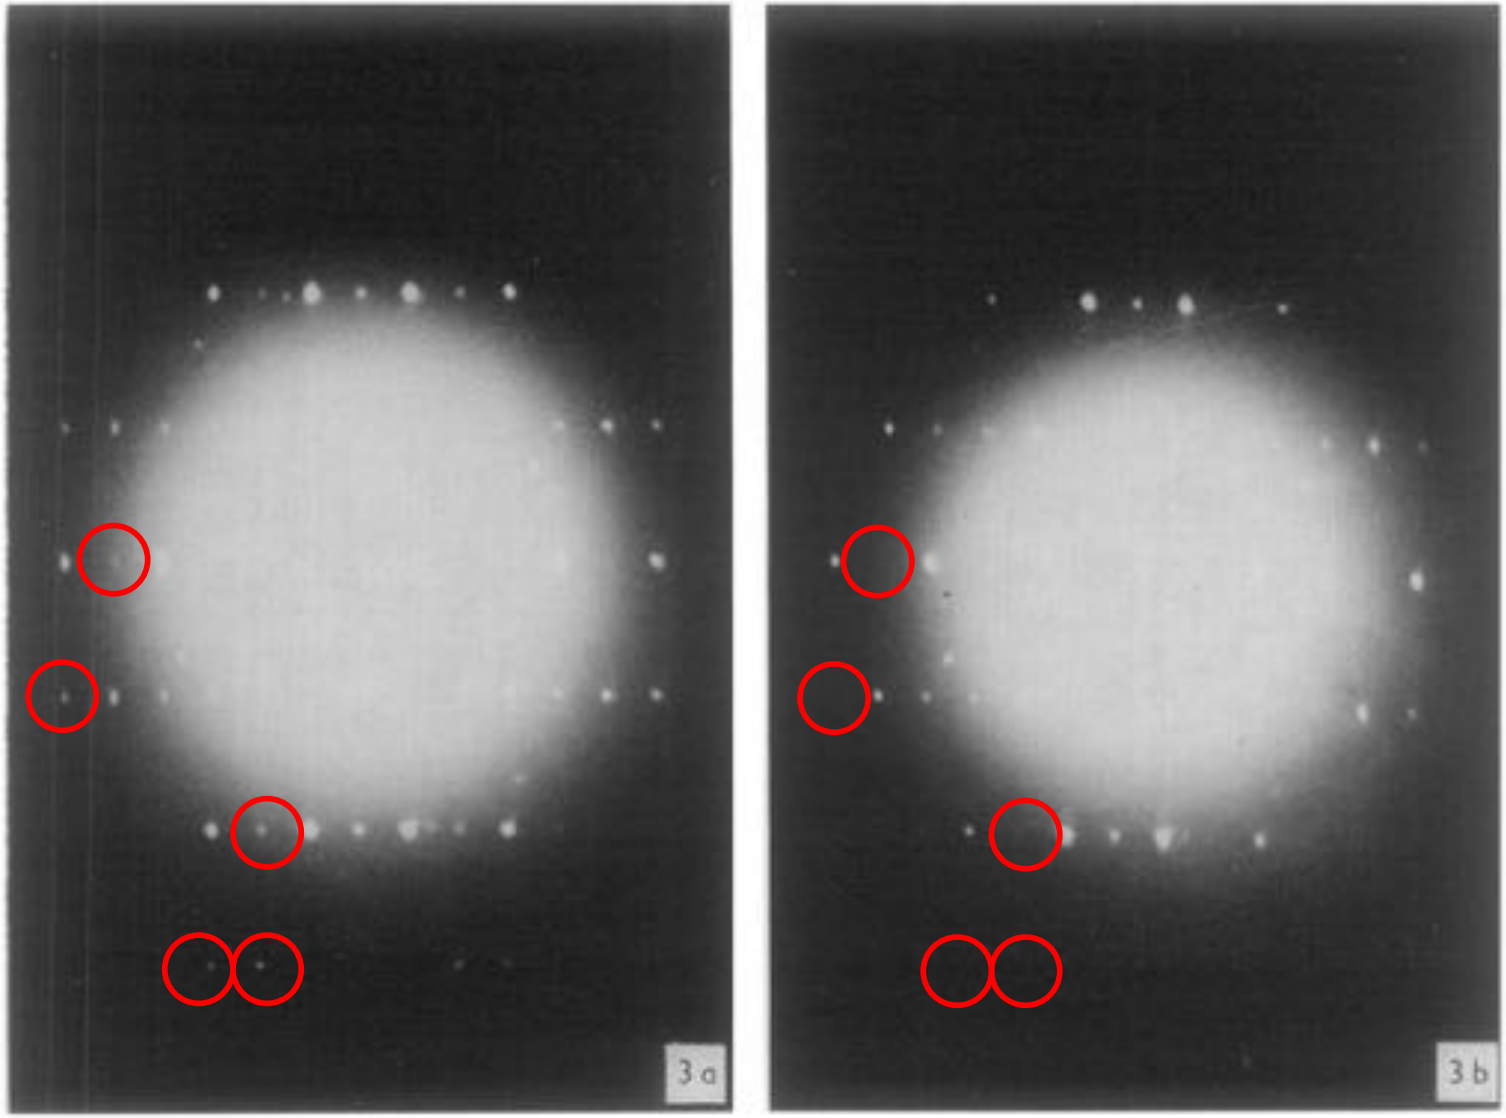

FIG. 3. The diffraction pattern of uranyl-acetate stained catalase is shown (a) before any significant changes have occurred and (b) after irradiating to a degree that no further changes occur. Reflections at Bragg spacings of less than 25 Å to 30 Å are no longer visible after so extensive an irradiation. Data were taken at 75 kV by the three-lens method (*7*) from a field approximately 10 μ in diameter.

Glaeser, R. M. (1971). Journal of Ultrasructure Research 36(3-4): 466-482.

Electron Diffraction of Frozen, Hydrated Protein Crystals

Abstract. *High-resolution electron diffraction patterns have been obtained from frozen, hydrated catalase crystals to demonstrate the feasibility of using a frozen-specimen hydration technique. The use of frozen specimens to maintain the hydration of complex biological structures has certain advantages over previously developed liquid hydration techniques.*

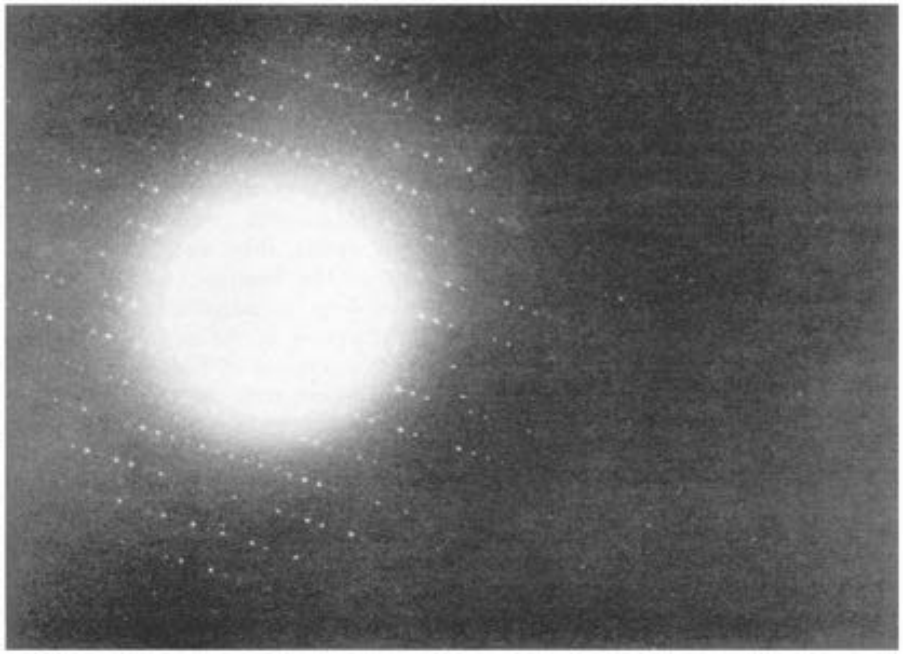

Fig. 1. Electron diffraction pattern of a catalase crystal which was frozen in liquid nitrogen and observed on a specimen stage cooled with liquid nitrogen. The resolution of the photographic reproduction is 4.5 Å, although that of the diffraction pattern on the original plate was 3.4 Å.

13 December 1974, Science 186:1036-37

In parallel to the work of Henderson and Unwin, Taylor and Glaeser discovered that biological specimen can be observed in a **frozen-hydrated state**. This discovery was not only key to advancing 2D-crystallography (and later being adopted by the X-ray community as well), but also made possible the study of single particles of large macromolecular complexes.

What does “frozen-hydrated” mean? It means that the sample is preserved in water!

How was it achieved?

Radiation damage and low temperature imaging

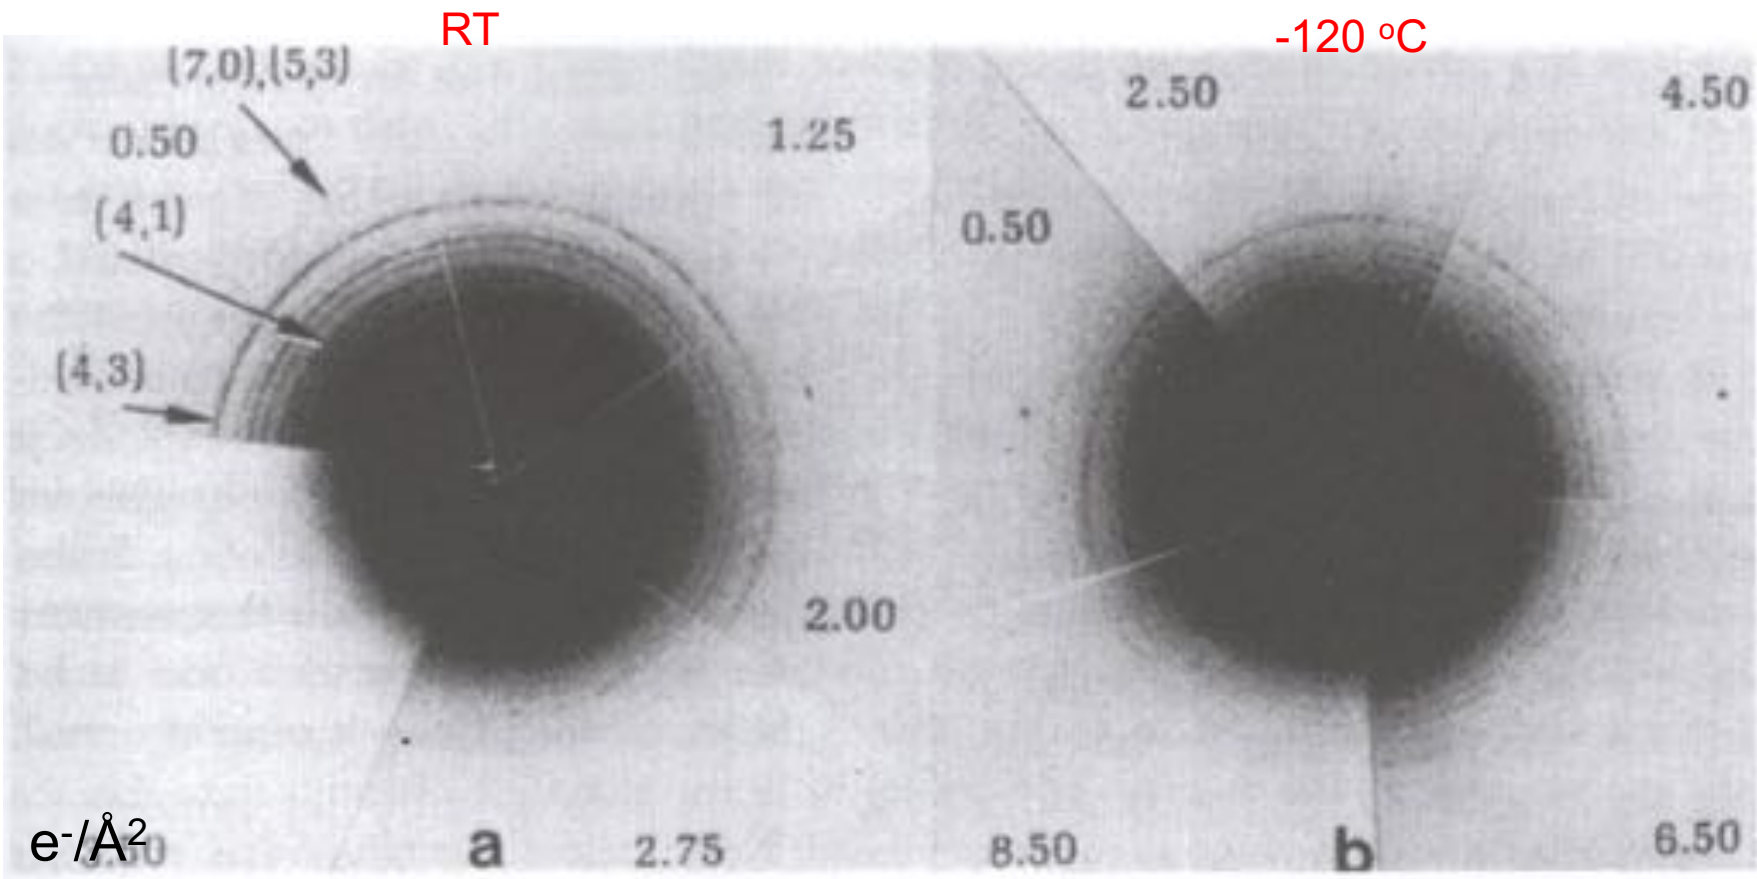

Figure 1.8 Comparison of the rate of fading of electron diffraction intensities at room temperature and at low temperature. A series of electron diffraction powder patterns of glucose-embedded purple membrane were recorded after specified periods of previously accumulated electron exposure (Hayward and Glaeser, 1979). The results show that about 5 to 7 times greater electron exposure can be tolerated at low temperature than at room temperature, for the same extent of specimen damage.

➔ Freeze sample in water and image at cryogenic temperature.

Vitrification of water

- Idea was proposed in late 1930s: Father B. Luyet proposed to cool a liquid so rapidly that molecules have no time to crystallize.
- Idea was not favorable: due to the discovery of the cryoprotecting effect of glycerol, ice crystals are allowed to grow but under controlled conditions.
  ➔ The vitrification of water was thought to be fundamentally impossible.
- Rapid development in 1980-1983
  - In 1974: Taylor and Glaeser, frozen catalase crystal (a drop between two grids was blotted and plunged into liquid nitrogen)
  - In 1981, Duboche group vitrified thin water layers, obtained by spreading on a support, by immersion in liquid ethane (Dubochet & McDowall, 1981)
  - In 1983, EMBO course to teach the vitrification method.

Why Ethane?

	Melting Point (°C)	Boiling Point (°C)	Heat of vaporization (kJ/kg)	Heat capacity (kJ/(kg·K)	Heat to boil (kJ/kg)	Heat to evaporate (kJ/kg)	Liquid density (kg/m3)
Nitrogen	-210	-196	6	0.9-1.6	13-22	19-28	809
Ethane	-183	- 89	489	2.3-3.5	216-329	705-818	546
Water	0	100	2257	4.185	418.5	2675.5	1000

Melt to boil

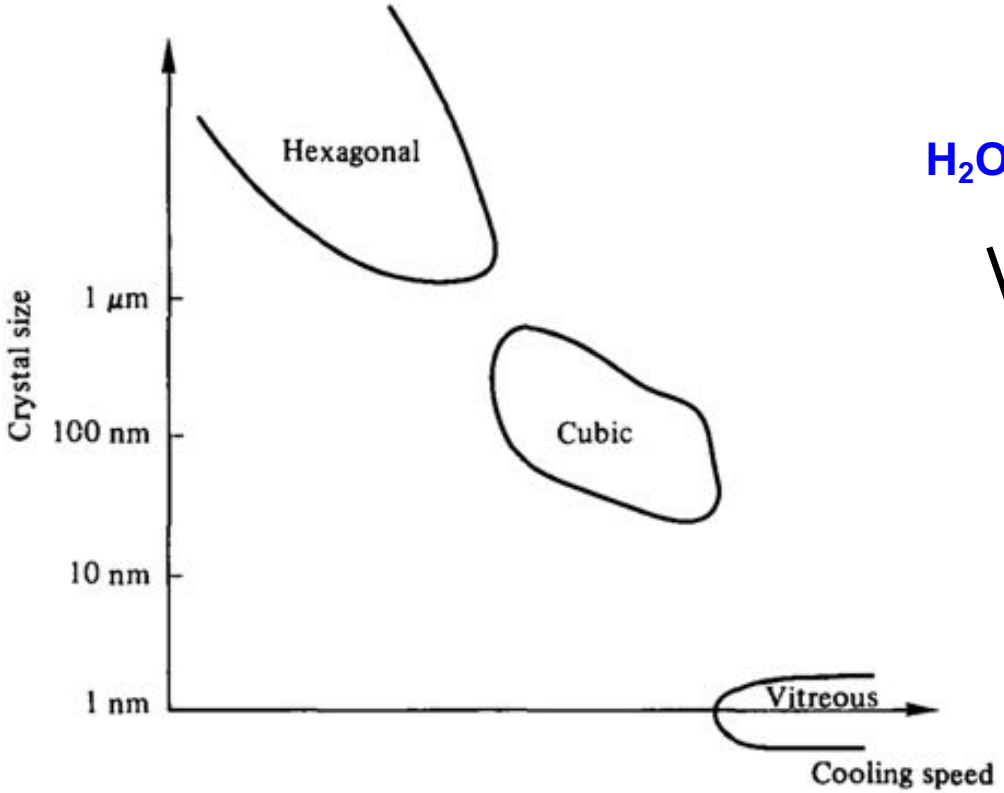
Melt to evaporate

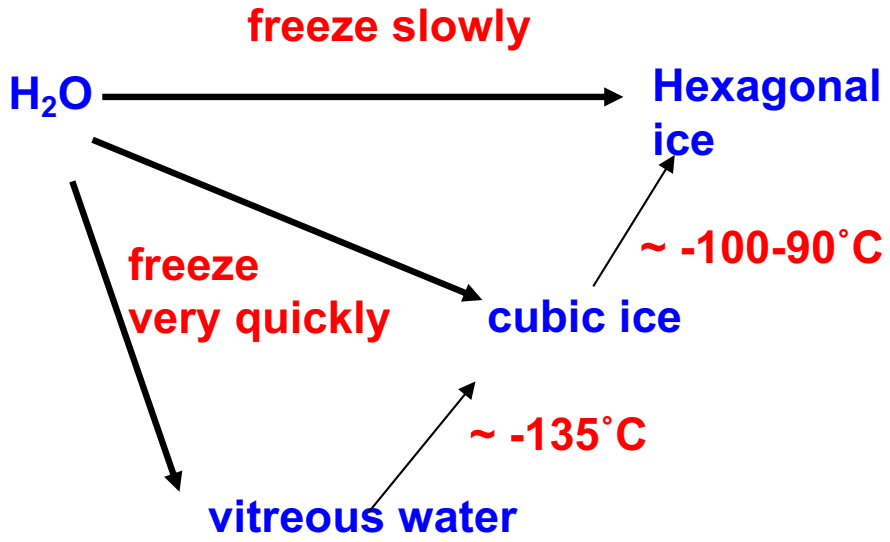
$Q=C^*\Delta T$

Boiling and evaporating of nitrogen produce a gas layer around the sample, thus prevent further freezing.

Vitrification of water

- Vitreous ice:
  An amorphous solid state in which water was frozen without adopting any crystalline structure.





Vitrification of water

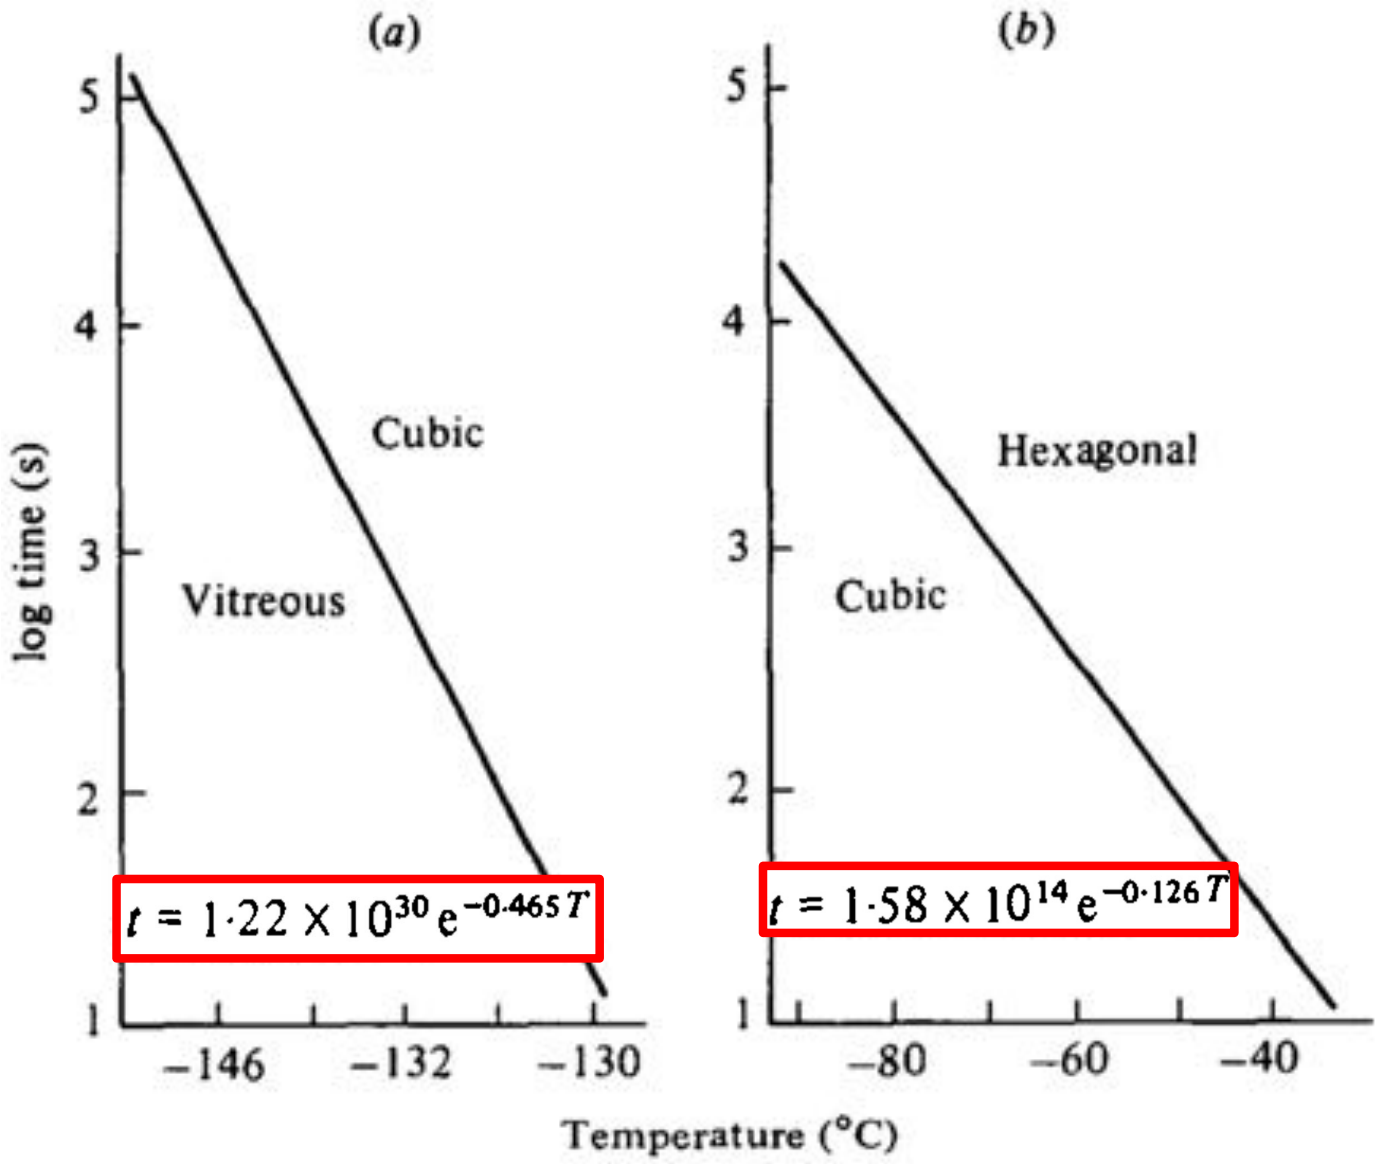


Fig. 6. Time t required, at the temperature T (° C), for the phase transition from (a) vitreous water to cubic ice and (b) cubic to hexagonal ice to take place (Dowell & Rinfret, 1960). Recent results suggest that curve (a) should be displaced by 10-20 ° C towards the higher values (see text).

Dubochet, J., Adrian, M., Chang, J. J., Homo, J. C., Lepault, J., McDowall, A. W. & Schultz, P. (1988). Cryo-electron microscopy of vitrified specimens. Quarterly Reviews of Biophysics, 21(2), 129-228.

Ice forms

3.66A/2.24A/1.91A

3.7A/2.1A

Fig. 5. Typical images and electron diffractograms of three forms of solid water observed in the electron microscope. The direct images and their diffractograms are all printed at the same scale, (a) Hexagonal ice obtained by **rapid freezing** of a water layer on a carbon film. The diffractograms, obtained from other specimens, show the (110) and (101) plane, (b) Cubic ice obtained by **warming a layer of vitreous water** obtained by condensation. The shoulder on the (111) reflection, possibly indicating the presence of a small amount of hexagonal ice, is marked by an arrow, (c) Vitreous water obtained in the microscope, by **condensation of vapour on a cold carbon film** supporting **polystyrene spheres**.

Table 2. *Main reflections in the electron diffractogram of the various forms of ice at −160 °C*

Hexagonal	Cubic	Vitreous	*d* (nm)	Intensity
100	—	—	0·389	Very strong
	—	First maximum	0·370	Very strong
002	111	—	0·366	Strong/very strong
101	—	—	0·343	Strong
102	—	—	0·266	Weak
110	220	—	0·224	Medium/medium
	—	Second maximum	0·214	
103	—	—	0·207	Medium
200	—	—	0·194	Very weak
112	311	—	0·191	Weak/weak
201	—	—	0·188	Very weak
202	—	—	0·172	Very weak

Ice contamination

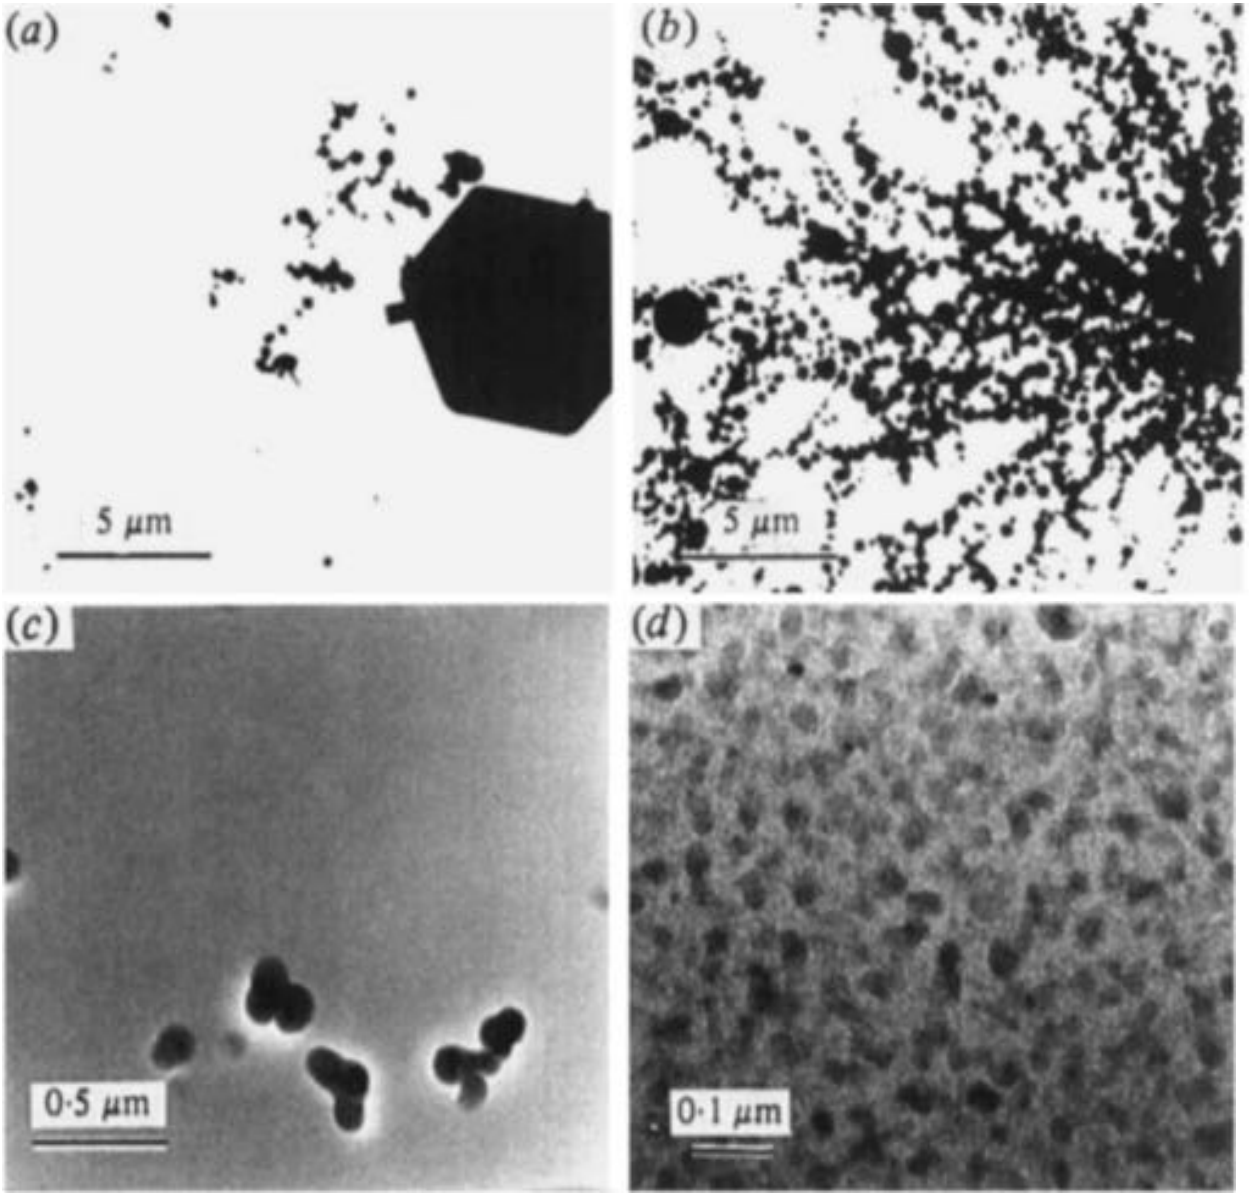

Fig. 32. Various forms of contamination on the specimen, *(a)* **Hexagonal ice** crystals **formed in humid air** and deposited during preparation of the specimen (in particular in the cryochamber of the microtome) and during transfer, *(b)* Agglomerate of **hexagonal ice** crystals **formed by humid air condensing on liquid nitrogen**, *(c)* Layer of **vitreous water deposited in the microscope**, on a thin vitrified film. **Hexagonal ice** crystals deposited on the specimen have been shadowed, thus revealing the contaminating layer and demonstrating that the water molecules came predominantly from one direction, *(d)* Crystals of **cubic ice** formed by deposition of water vapour in the microscope in a similar but **more rapid way** than in *(c)*.

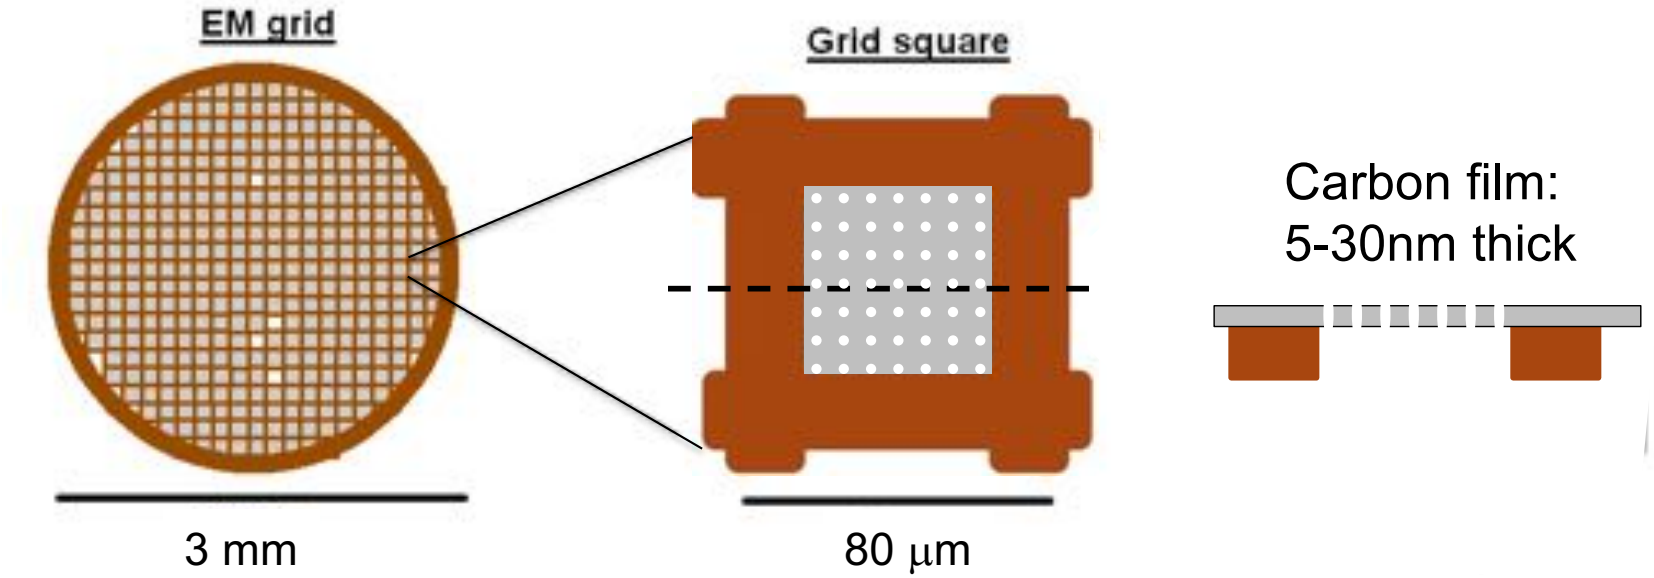
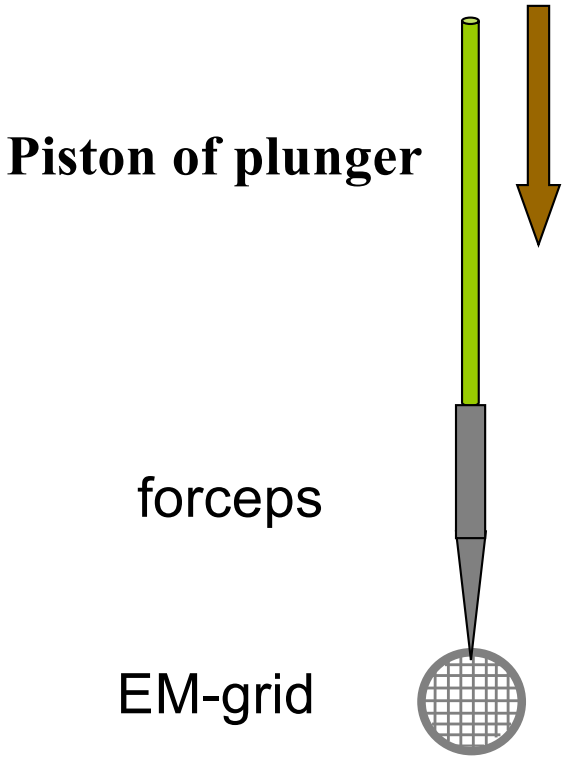
TEM grids



An EM grid coated with a thin carbon film (5-30 nm).

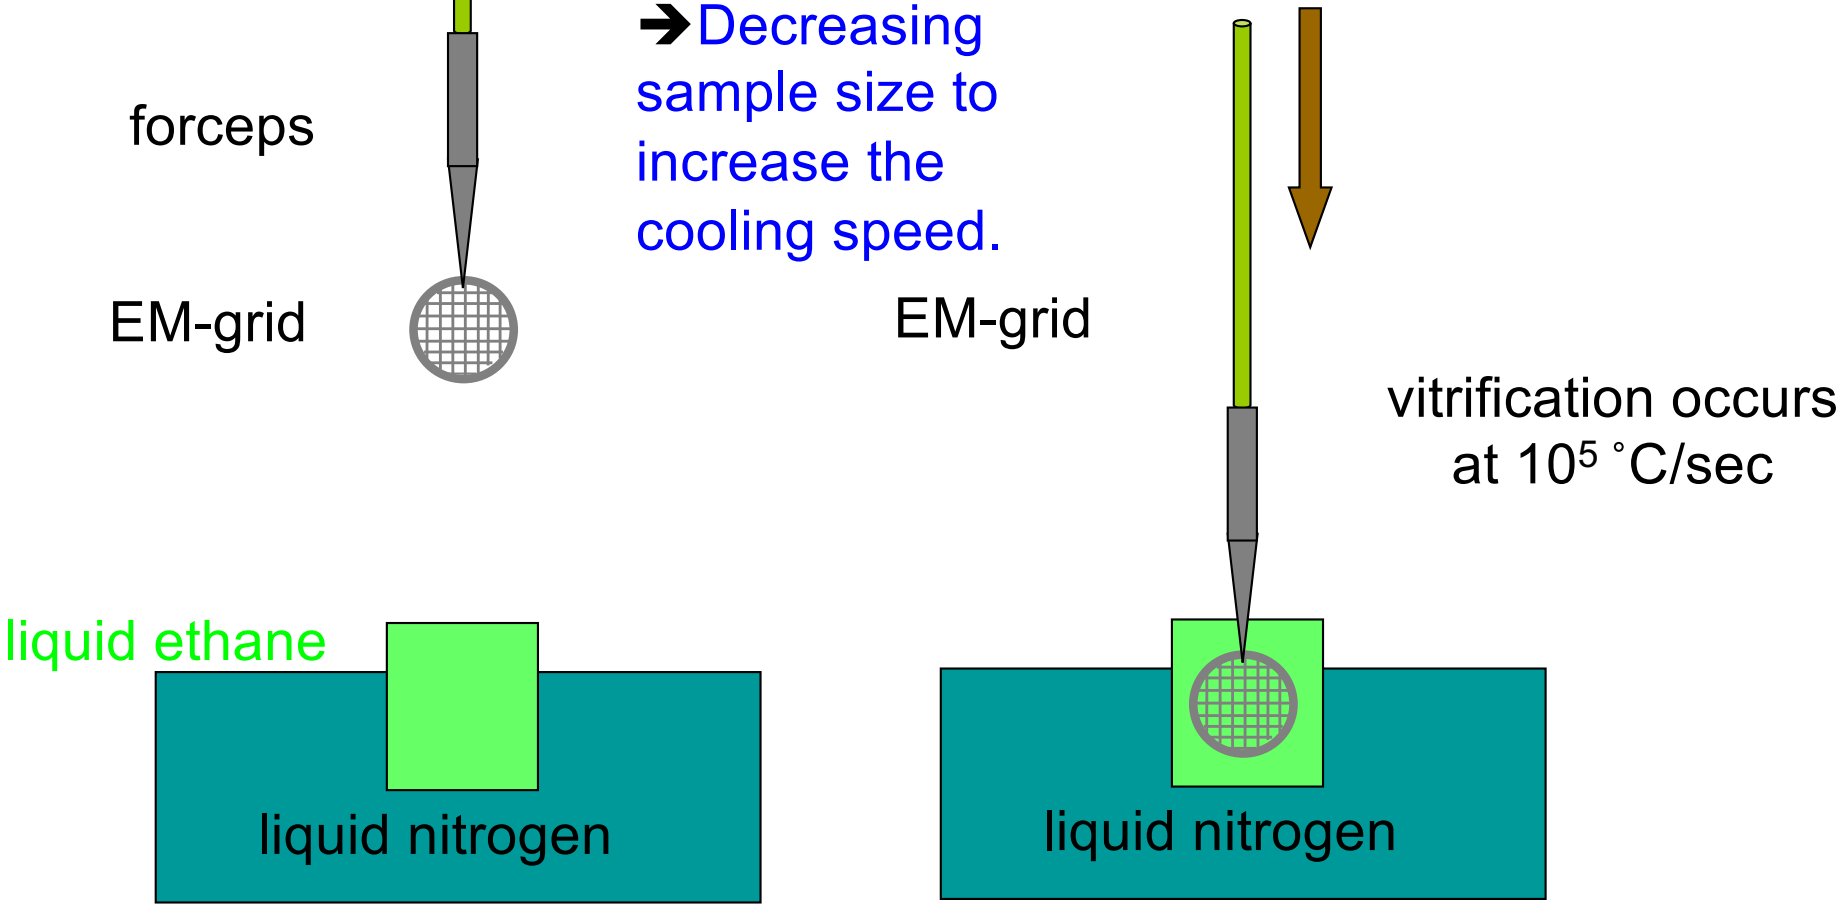
400 mesh: 400 squares in 1 inch➔2.54cm/400=63.5 microns

Sample Vitrification



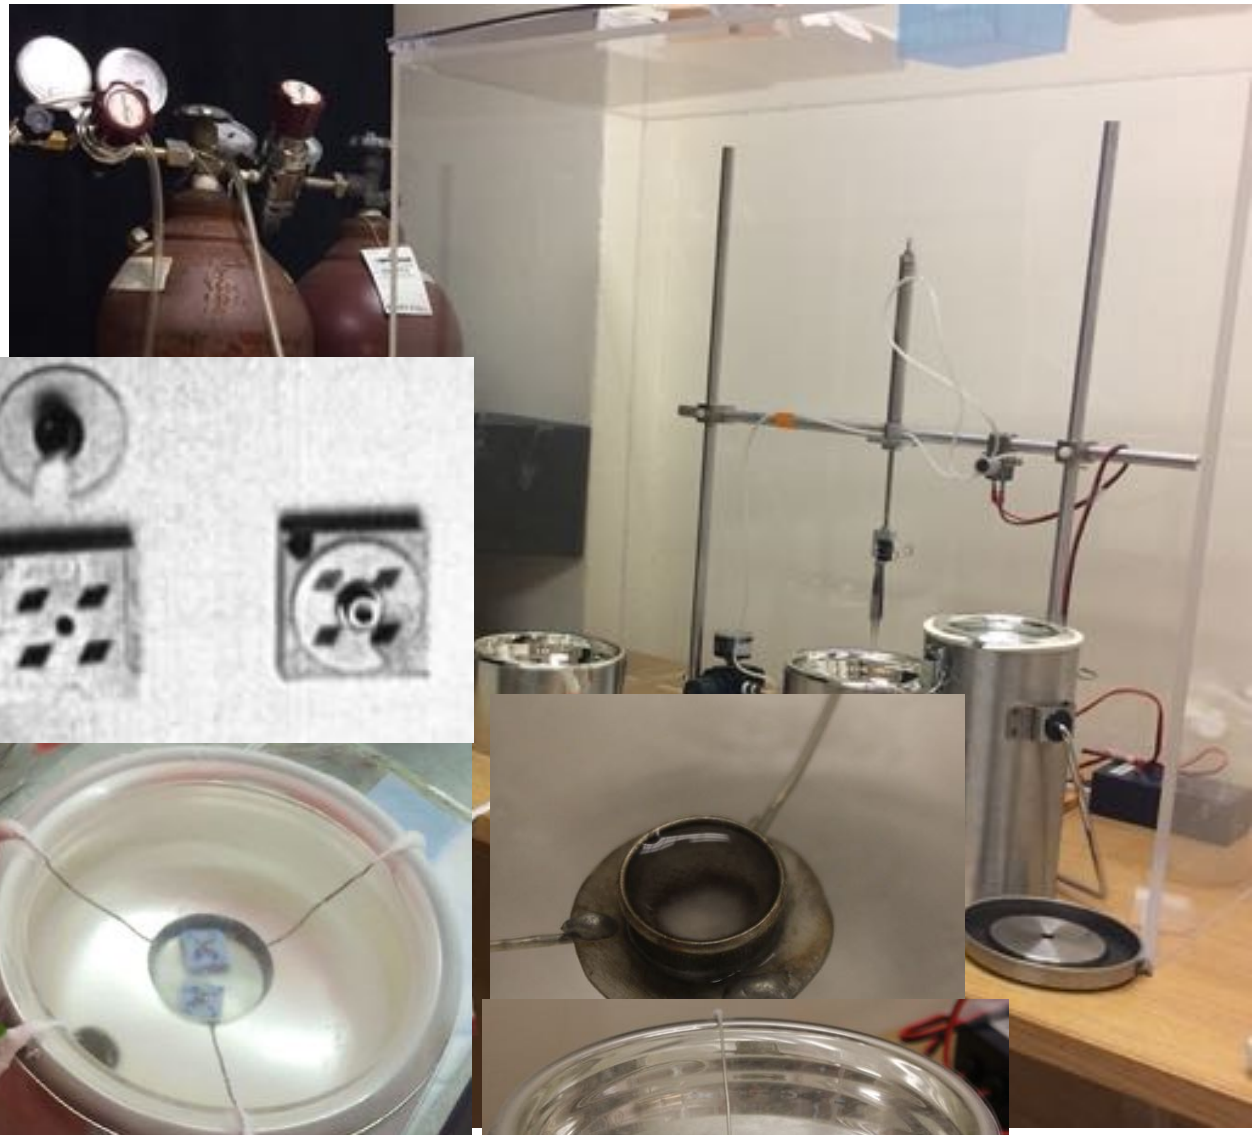
Need high relative humidity in environment because at wind velocities of ~1m/s and 4˚C the rate of natural water evaporation is: ~52Å/second (99% humidity) but ~1000Å/second at 80% humidity. At room temperature, this rates are about 4-fold higher!

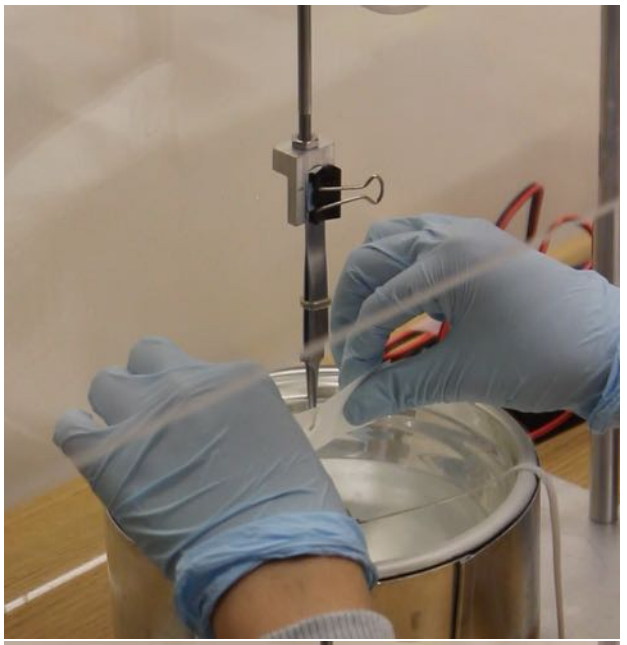
➔Decreasing sample size to increase the cooling speed.

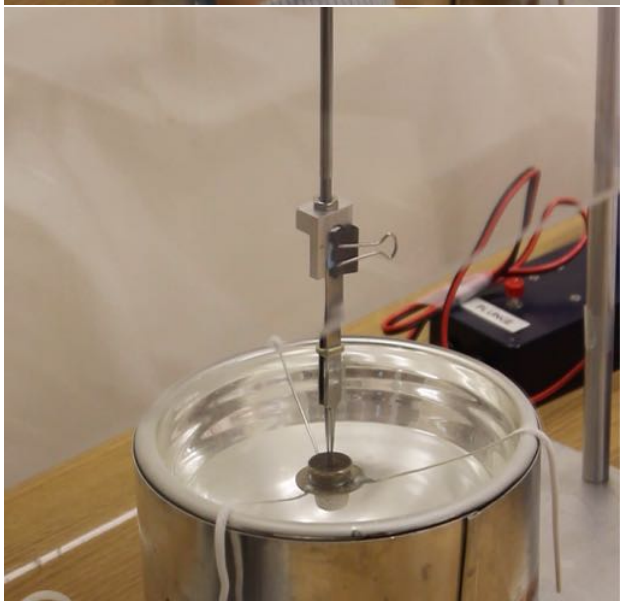


vitrification occurs at 10^5 ˚C/sec

Freezing of samples







Water evaporation

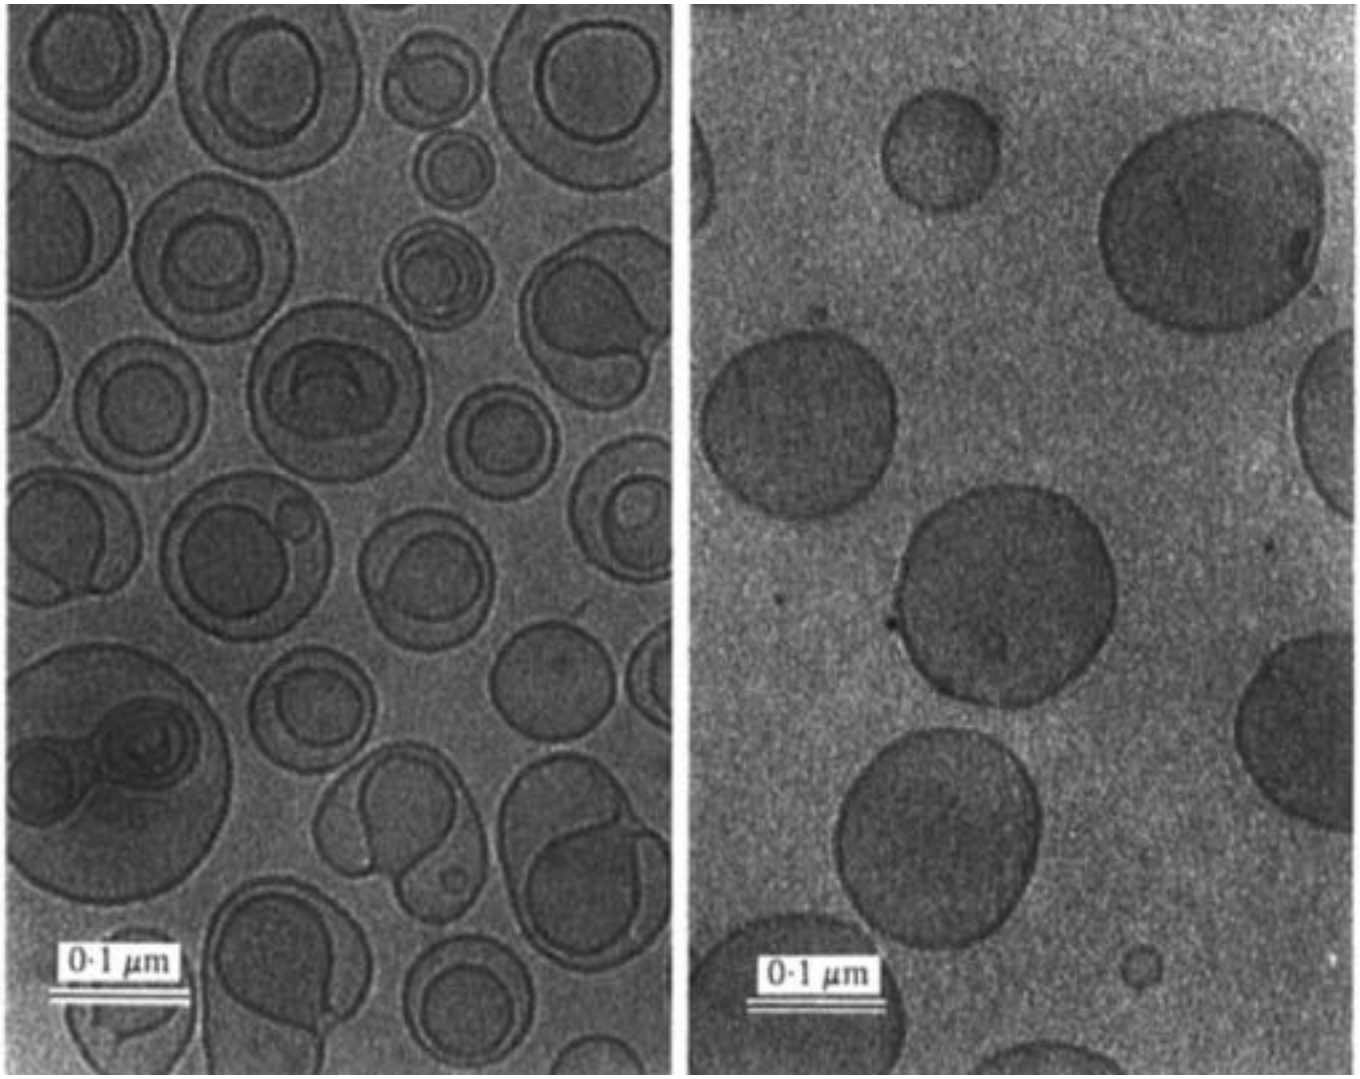


Fig. 24. Solution of lipid vesicles in 100 mM-NaCl. *(a)* The specimen has been prepared by the bare-grid method under conditions where part of the water evaporates before the thin film is vitrified. Invagination of the vesicles and formation of concentric vesicles reveal the osmotic effect due to the rapidly changing salt concentration in the liquid, *(b)* The same sample prepared in saturated humidity does not show osmotic effects.

Dubochet J, et al. 1988. Q Rev Biophys 21:129-228.

Bubbling and radiation damage

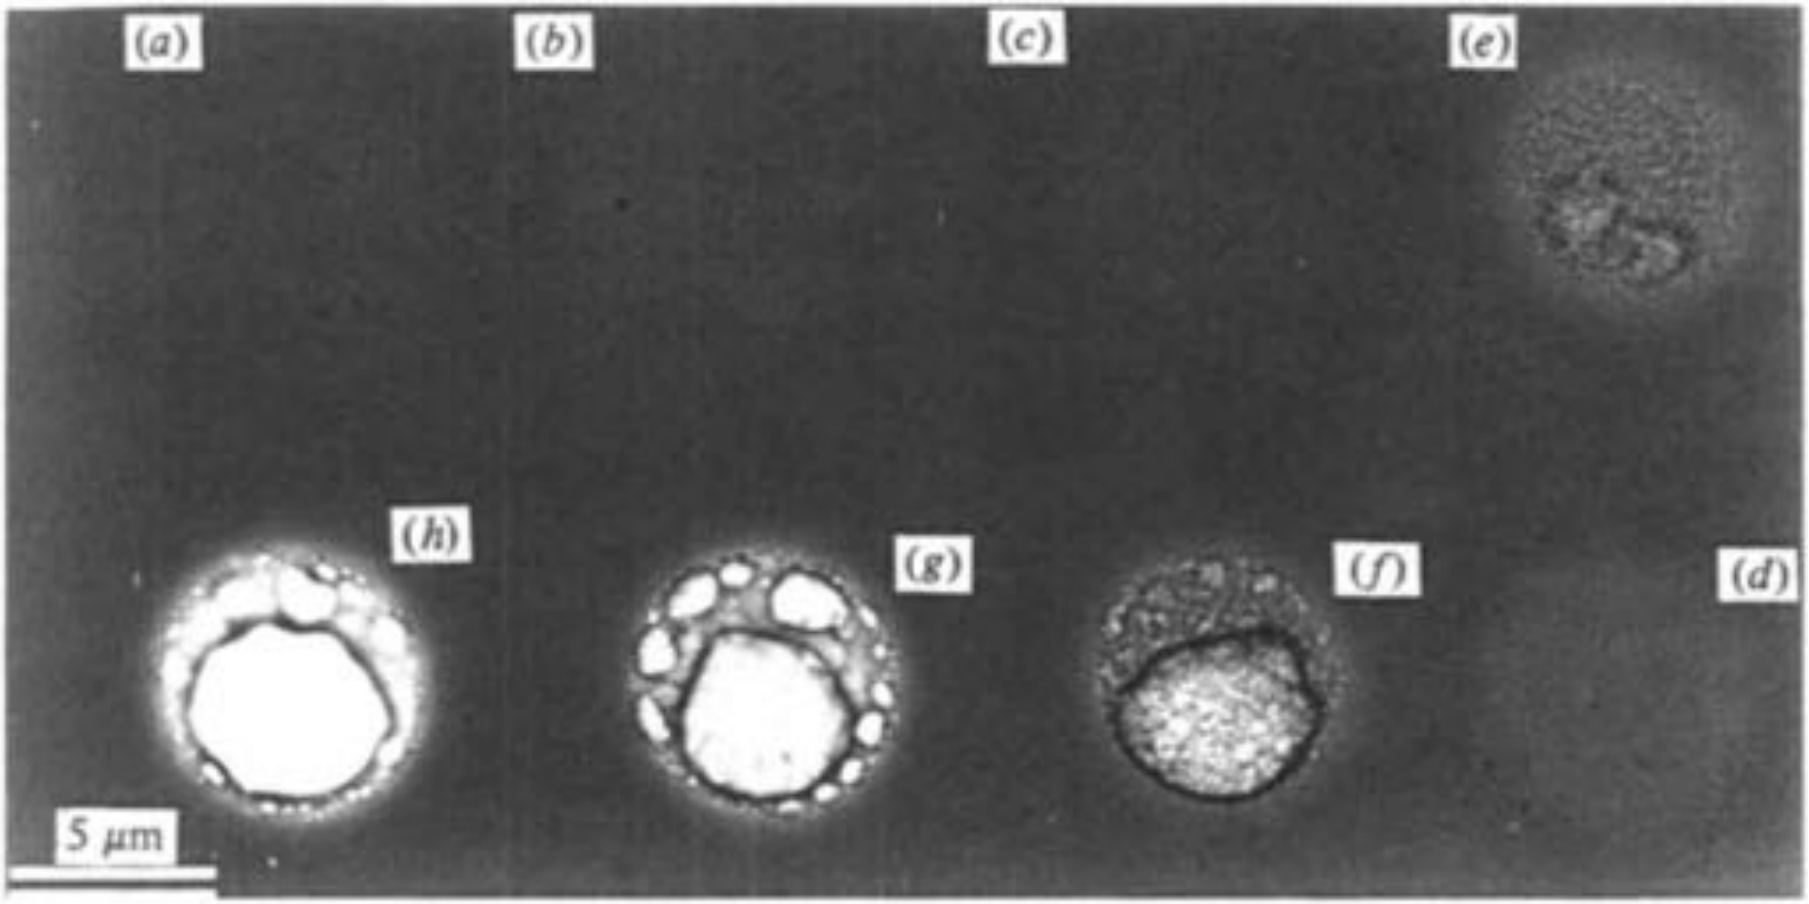

Fig. 37. Bubbling on a carbon-coated formvar film c. 10 nm thick, covered with a layer of condensed vitreous water. Fields (a)-(h) correspond to irradiations by 5, 20, 40, 80, 120, 240, 340 and 450 ke/nm2 respectively. The total thickness of the specimen is 160 nm.

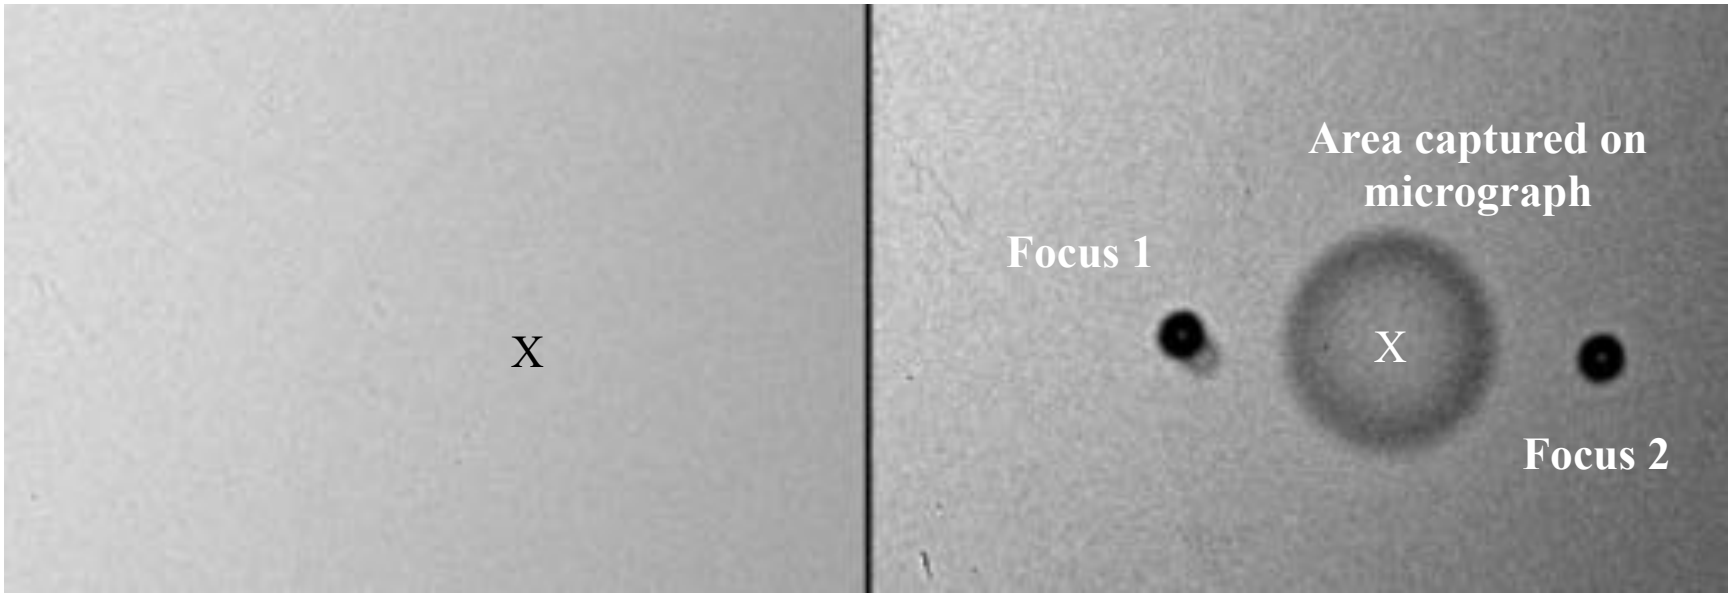
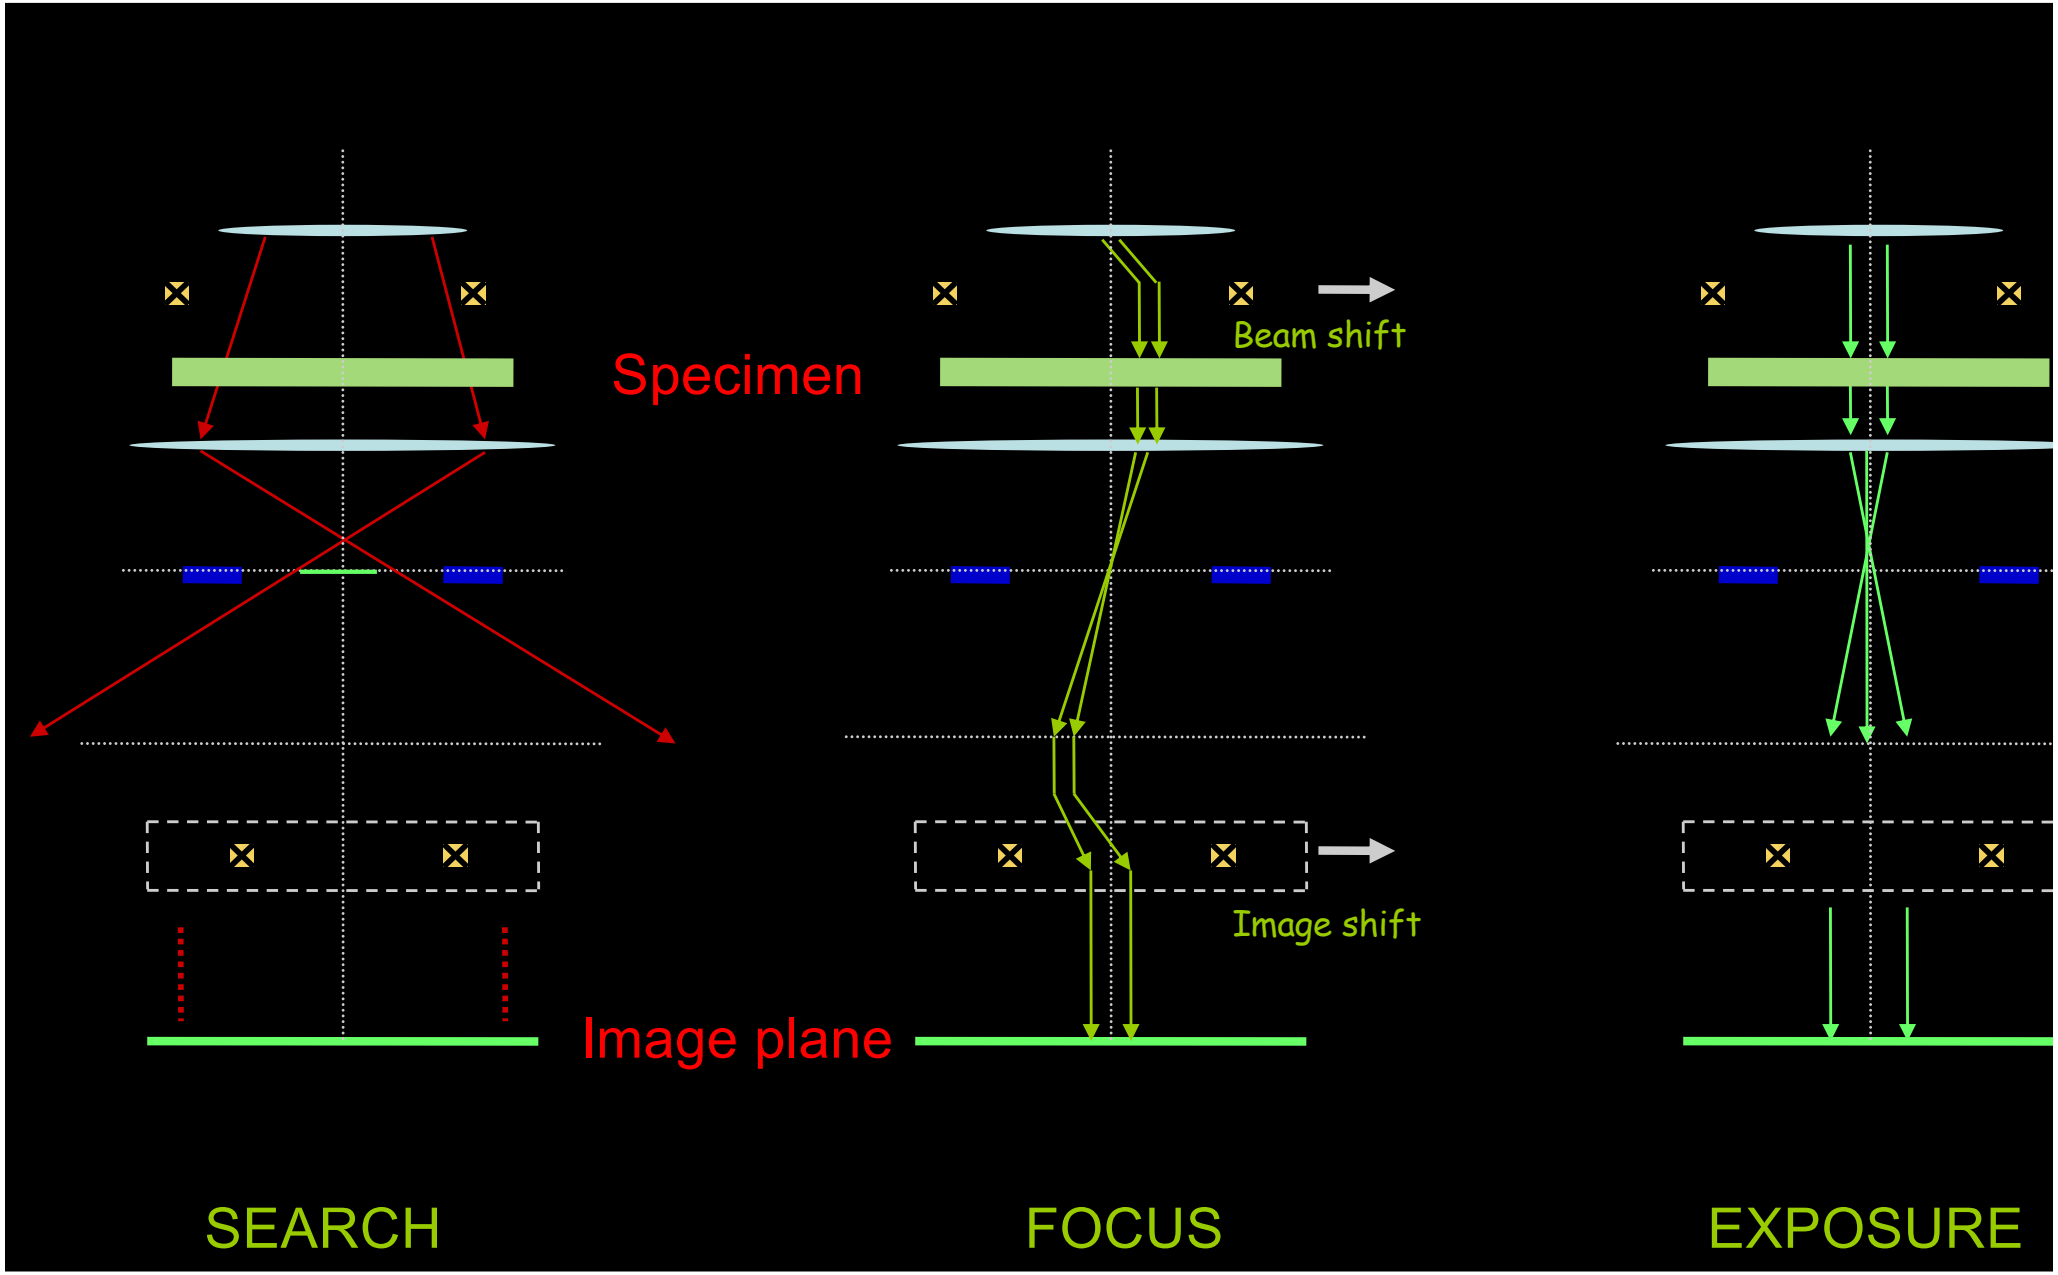
Principle Of Low-Dose Microscopy

- Search regions of interest (ROIs)
- Focus at ROIs
- Image ROIs (exposure)



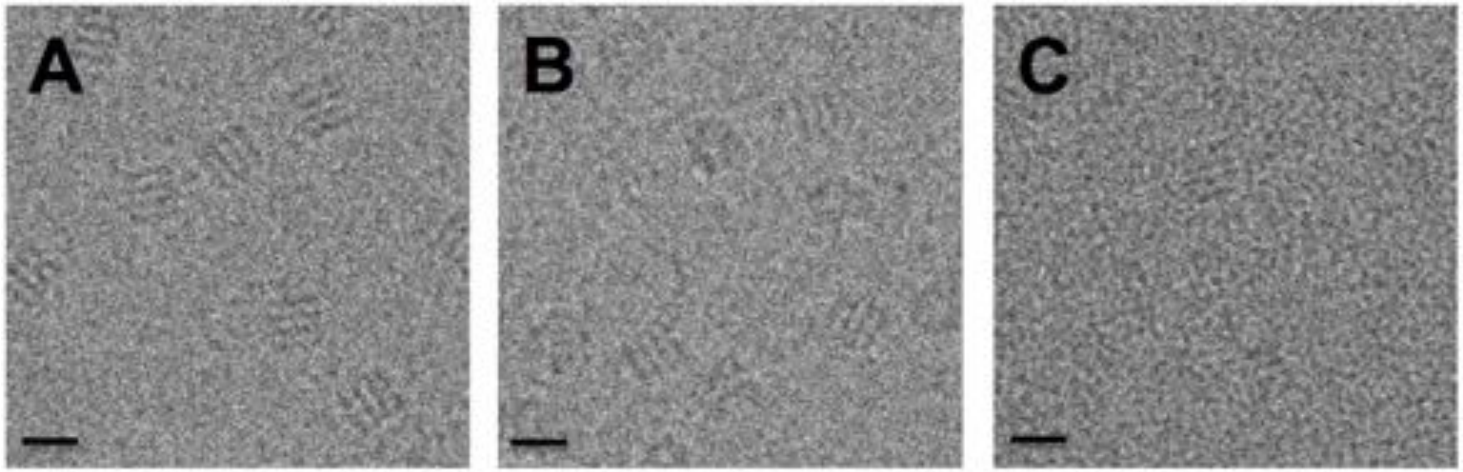
Appearance of trehalose dried down on a carbon film (left). The sugar allows to demonstrate how "low-dose" microscopy is done (right). Let X be the area of interest (for instance a crystal or virus/single particle). Prior to taking a picture some parameters such as "defocus" and "astigmatism" need to be adjusted. To avoid destruction of the specimen, any adjustments are made on small areas (Focus 1 and 2) located adjacent to the area that will be photographed. In the example, the trehalose burned as it was exposed at high magnification (220kx, Focus 1 and 2). Similarly, by exposing the area to be captured for about 30 seconds at 52,000 fold magnification.

Electron optics of Low-Dose imaging

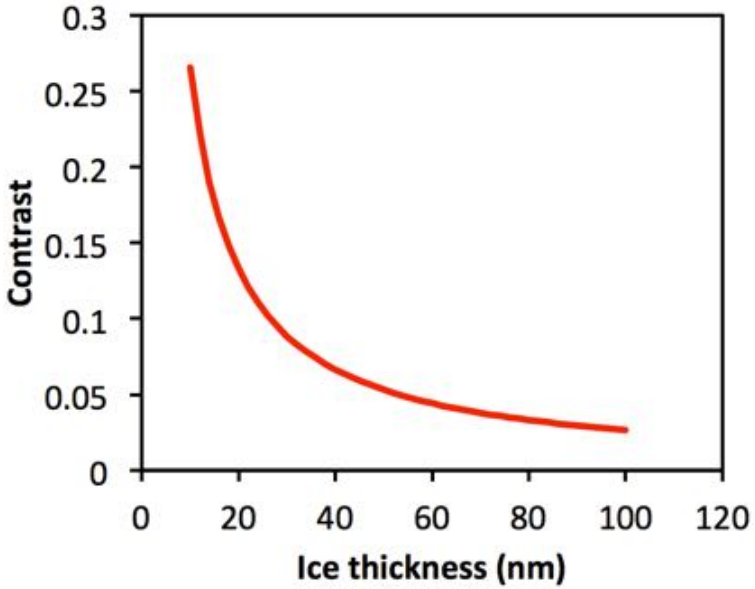


Ice thickness affects image contrast significantly

CryoEM images of GroEL



The reported ice thickness shown in B and C are 150% and 200% of the ice thickness shown in A.



$$C = \frac{\Delta I}{I_s} = \frac{(\phi_{protein} - \phi_{water}) \bullet t_{protein}}{\phi_{water} \bullet t_{ice}}$$

where $\phi_{protein}$ and ϕ_{water} are phase shifts of electrons passing through protein and water regions, and $t_{protein}$ and t_{ice} are thickness of protein molecules and ice layer, respectively

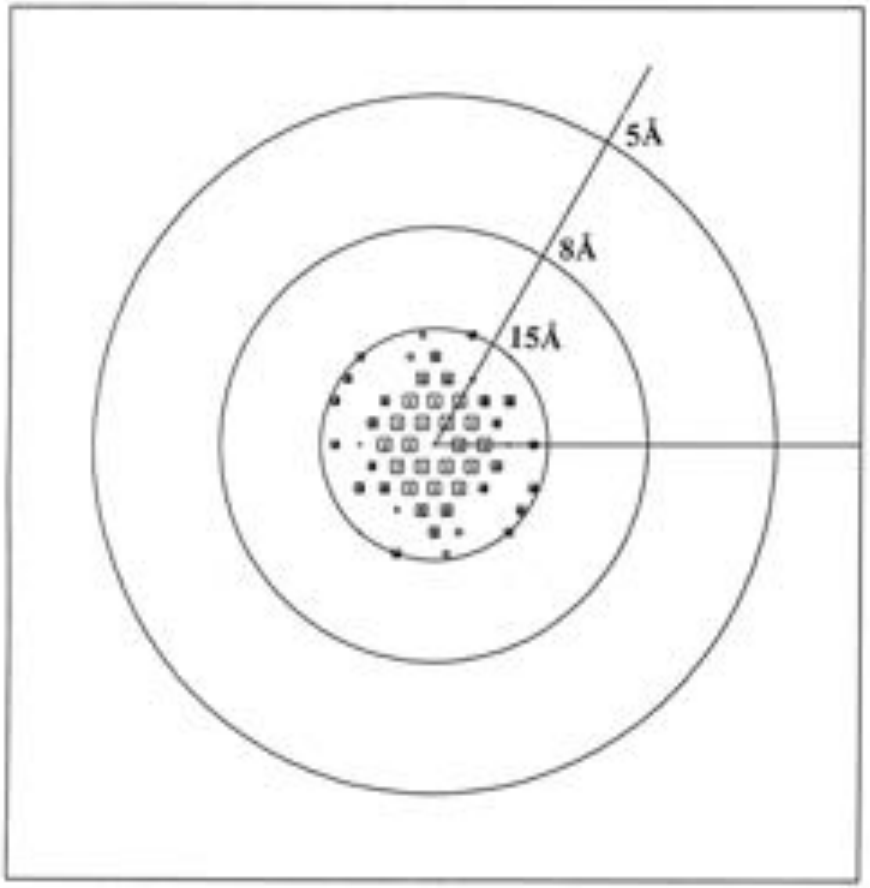
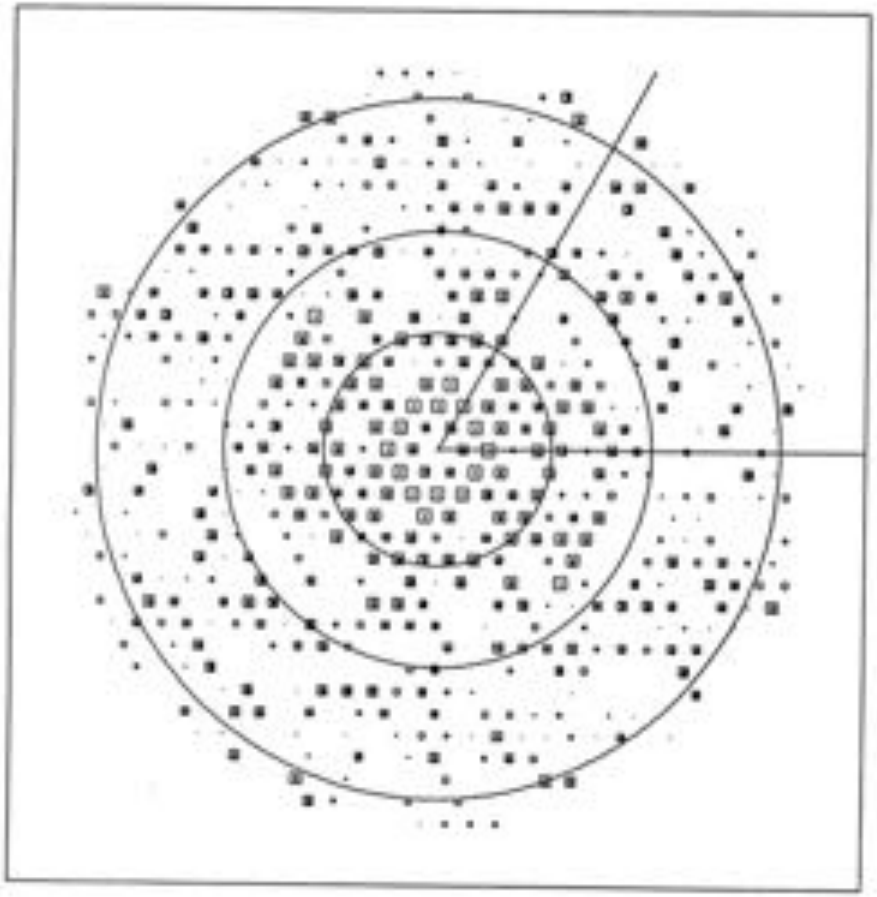
Comparison: Negative Stain vs Vitrification

Negative Stain

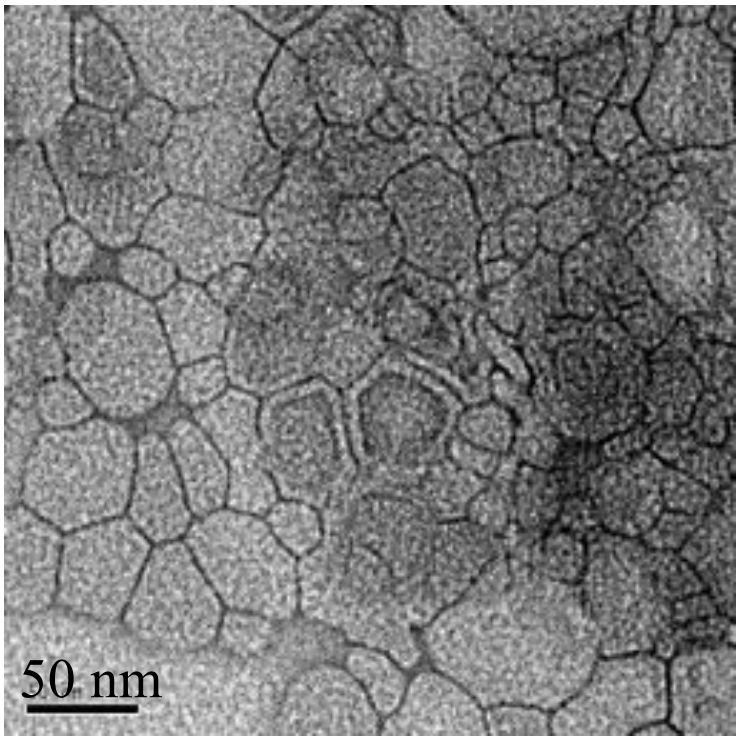


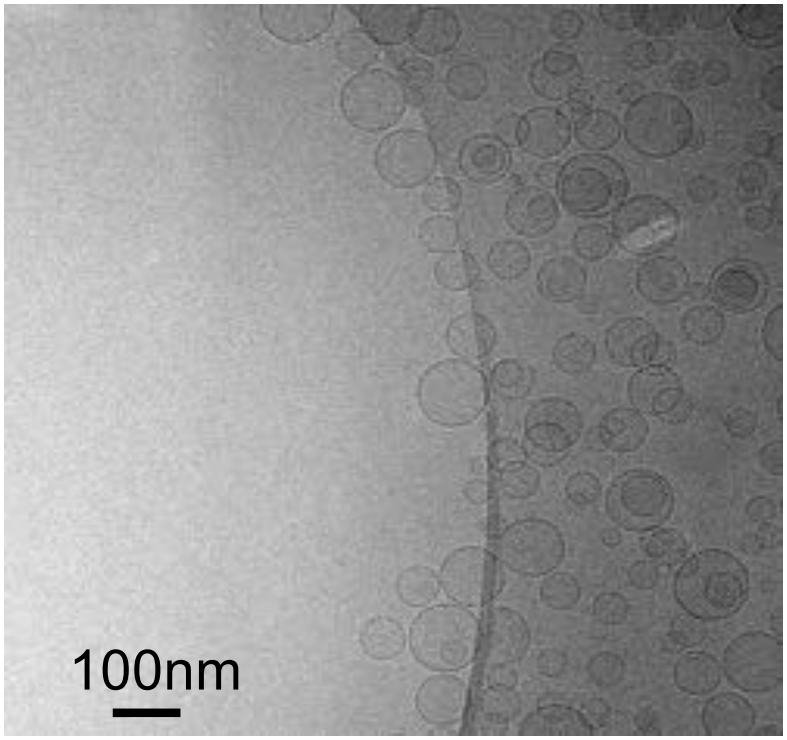
Frozen-Hydrated

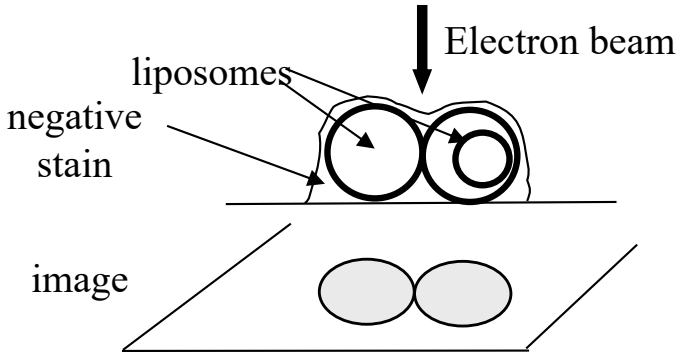


Data shown were obtained from 2D-crystals of gap-junction channels

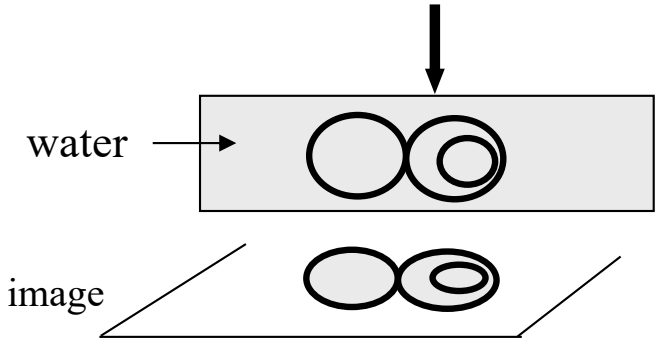
Negative Stain vs Frozen-Hydrated







No internal detail/features



Internal detail/features are revealed

Summary of specimen preservation techniques

Negative Staining (embedding in salts of heavy metals [e.g. Uranyl acetate, tungsten])

- Easy & fast
- Good reproducibility
- Radiation damage can be seen, but not so critical

- Resolution limited to ~15Å
- No internal feature can be seen
- No time resolution (unless very slow)
- Specimen may be denatured by stain (Drying and flattening artifact)

Vitrification (embedding in vitreous water or small organic substances [e.g. trehalose, glucose])

- See protein directly including internal features
- No drying / flattening artifact
- Resolution can be 1.2 Å
- Time resolved studies possible (ms - minute range)

- Not so easy to do
- More radiation sensitive
