

16 **Key points:**

- 17 1. The accretion process plays more important roles than other examined liquid-
18 phase processes.
- 19 2. Considering raindrop size in accretion process suppresses liquid-phase rain and
20 mitigates the overprediction of precipitation over the TP.
- 21 3. Increasing the model resolution can reduce precipitation overprediction.
- 22

23 **Abstract**

24 Numerical simulations often overpredict precipitation over the Tibetan Plateau. To
25 examine the factors causing precipitation overprediction, a typical summer plateau
26 precipitation event is simulated with the Weather Research and Forecasting (WRF)
27 model by exploring different parameterizations of liquid-phase microphysical
28 processes into the commonly used Morrison scheme, including autoconversion,
29 accretion, and entrainment-mixing. All simulations can reproduce the general spatial
30 distribution and temporal variation of precipitation, but overpredict precipitation rate.
31 The results show that the accretion process is more important than other examined
32 liquid-phase processes in simulating precipitation. Further investigation reveals that
33 accretion parameterization that takes into account the raindrop size produces the most
34 accurate results in terms of the total surface precipitation, which is supported by the
35 Heidke skill scores. Such parameterizations suppress spurious accretion and liquid-
36 phase precipitation when cloud droplets are too small to initiate precipitation. It is also
37 confirmed that increasing the model resolution can reduce precipitation overprediction.
38 Results from the case study are confirmed by use of a one-month simulation.

39

40 1. Introduction

41 The Tibetan Plateau (TP) is the highest and largest plateau of the world with an
42 average elevation of more than 4 km above the sea level and an area larger than $2.5 \times$
43 10^6 km². Its active exchanges of heat and moisture have significant influences on
44 climate and environmental change, not only in China but also over East Asia and even
45 the entire northern hemisphere through strong thermal and dynamic forcing (*Yeh*, 1950;
46 *Flohn*, 1957; *Hahn and Manabe*, 1975; *Ye*, 1981; *Wu and Chen*, 1985; *Yanai et al.*, 1992;
47 *Ding et al.*, 2001; *Wang et al.*, 2008; *Molnar et al.*, 2010; *Yang et al.*, 2014; *Qie et al.*,
48 2005; *Fu et al.*, 2006; *Li and Zhang*, 2017; *Li et al.*, 2020). Many studies have reported
49 that the tropospheric heating over the TP has decisive effects on the maintenance of the
50 Asian summer monsoon (*Luo and Yanai*, 1983; 1984; *Ueda and Yasunari*, 1998). The
51 upward transport of sensible heat and the release of latent heat due to convective clouds
52 are important heat sources in the upper troposphere, driving the summer monsoon and
53 associated precipitation (*Nitta*, 1983; *Luo and Yanai*, 1984; *Yanai and Li*, 1994; *Ueda*
54 *et al.*, 2003; *Hsu and Liu*, 2003; *Fan et al.*, 2013; *Jiang et al.*, 2004; *Li et al.*, 2013).

55 During the summer monsoon, deep convection develops over the TP with a marked
56 diurnal cycle in precipitation (*Fujinami and Yasunari*, 2001; *Kurosaki and Kimura*,
57 2002; *Chen et al.*, 2017a), frequently associated with mesoscale vortices (*Shen et al.*,
58 1986; *Wang et al.*, 1993; *Li et al.*, 2008b). Summer precipitation on the plateau can be
59 characterized by frequent, but rather weak convection (*Li et al.*, 2008b; *Li and Zhang*,
60 2016; *Gao et al.*, 2016; *Chen et al.*, 2017a). Undoubtedly, these characteristics are

61 heavily influenced by the unique terrain of the TP (*Porcù et al.*, 2014; *Chen et al.*, 2017b;
62 *Wu and Liu*, 2017).

63 The particularity of the TP makes it one of the most challenging areas for
64 precipitation simulation. Many studies find simulated precipitation to be overpredicted
65 (*Maussion et al.*, 2011; *Xu et al.*, 2012; *Gao et al.*, 2016). There are several reasons for
66 this overprediction, including model resolution (*Sato et al.*, 2008, *Xu et al.*, 2012) and
67 the initial and boundary conditions (*Gerken et al.*, 2013). Moreover, the assumptions in
68 the parameterization of microphysics could be another culprit for the overprediction of
69 precipitation over the TP region. *Maussion et al.* (2011) found a significant sensitivity
70 to changing the microphysics parameterization for convective precipitation over the TP.
71 They compared different physical schemes with different statistical evaluation scores
72 and the results showed that the effects of microphysics schemes were larger than other
73 physical schemes including cumulus schemes, land surface schemes, and boundary-
74 layer schemes.

75 The high elevation of the TP, and hence the typically low melting level, enables
76 plenty of supercooled liquid water, even in summer (*Gao et al.*, 2016; *Zhao et al.*, 2017;
77 *Tang et al.*, 2019). Therefore, it is likely that liquid precipitation processes play a role
78 in the precipitation overestimation in this region. For instance, *Zhao et al.* (2017)
79 confirmed that supercooled cloud water dominated in precipitating cumulus clouds over
80 the Naqu area at a temperature of -2.5 to -3.5°C. By analyzing the raindrop size
81 distribution at Maqu over the TP, *Li et al.* (2006) argued that liquid-phase processes

82 were important for surface precipitation, despite dominant ice/mixed-phase rain
83 processes over the region. *Gao et al. (2016)* investigated the role of liquid-phase
84 processes by excluding ice-phase microphysics, doubling the condensation rate,
85 halving the evaporation rate and increasing the initial droplet radius, and found
86 significant effects from all these sensitivity tests on the surface precipitation; they also
87 suggested that liquid-phase rain processes could be more important than ice-phase
88 processes over the precipitation cores during weak convection over the TP.

89 However, it is still unknown how liquid-phase processes affect precipitation over
90 the TP, and whether improving the parameterizations of liquid-phase processes can
91 mitigate the problem of overpredicted precipitation. Also unknown is which liquid-
92 phase process is the most important in affecting TP precipitation, and which
93 parameterization can best describe the most important process and why. This study fills
94 these gaps by comparing simulations of a typical precipitation event over the TP with
95 different parameterizations of autoconversion, accretion, and entrainment-mixing
96 processes (hereafter referred to as liquid-phase processes for convenience) and
97 dissecting the underlying physical mechanisms. This is done using a case study, as well
98 as a one-month simulation. Moreover, the impact of model resolution is investigated
99 following *Sato et al. (2008)* and *Xu et al. (2012)*.

100 Three parameterized liquid-phase processes related to precipitation are
101 investigated in this paper: autoconversion, accretion, and entrainment-mixing. These
102 three processes are likely to be intertwined. It is expected that accretion and ice/mixed-

103 phase processes matter in the precipitation events over TP. But also, autoconversion and
104 entrainment-mixing process may be important. The reason is that accretion is the
105 collection process between liquid raindrops and cloud droplets, and the number
106 concentration and size of liquid droplets are affected by autoconversion and
107 entrainment-mixing process. Autoconversion is expressed as the mass conversion rate
108 from cloud to rain due to the collision-coalescence of cloud droplets while accretion is
109 defined as the rate of mass conversion from cloud to rain due to the collection of cloud
110 droplets by raindrops (*Wood et al., 2009; White et al., 2017; Liu and Daum, 2004; Liu*
111 *et al., 2011; Jing et al., 2019; Fan et al., 2016; Wang et al., 2019b*). The sum of
112 autoconversion and accretion is calculated as the total mass conversion from cloud to
113 raindrop populations during the collision-coalescence process (*Wood, 2005b*). *Wang et*
114 *al. (2012)* and *Gettelman et al. (2013)* highlighted that autoconversion was important
115 for the initiation of precipitation whereas accretion was responsible for the amount of
116 precipitation. The process of entrainment and mixing between cloud and environment
117 is one of the most uncertain processes in cloud physics (*Kollias and Albrecht, 2000;*
118 *Grabowski, 2006; Lu et al., 2013; Hoffmann and Feingold, 2019; Gao et al., 2020*). The
119 key issue of the entrainment-mixing process is whether evaporation due to mixing
120 causes a reduction of only droplet size (homogeneous mixing), only droplet number
121 (extremely inhomogeneous mixing), or both. Therefore, different entrainment-mixing
122 mechanisms can affect cloud microphysical properties and hence cloud-related
123 processes such as radiation and precipitation (*Lasher-Trapp et al., 2005; Grabowski,*

124 2006; Chosson *et al.*, 2007; Slawinska *et al.*, 2008; Cooper *et al.*, 2013; Lu *et al.*, 2013).

125 This paper is organized as follows: A brief introduction of the precipitation event
126 and experimental setup are given in section 2. Section 3 discusses the influences of
127 liquid-phase processes on precipitation overprediction and underlying physical
128 mechanisms. Section 4 extends the case study to one-month simulations. The effects of
129 resolutions on precipitation overprediction are discussed in section 5. Section 6 presents
130 the summary and conclusions.

131

132 **2. Precipitation event, experiment description, and method**

133 **2.1 Case description and observations**

134 As mentioned in Gao *et al.* (2016), the entire plateau experienced a large frontal
135 system from 21 to 23 July 2014 and observed precipitation initiated at 0400 UTC
136 (Coordinated Universal Time) 22 July. The motivation of using this case is that WRF
137 can capture the main precipitation pattern (Gao *et al.*, 2016). Gao *et al.* (2016) and this
138 study focus on different periods and different scientific questions. As mentioned in the
139 introduction, Gao *et al.* (2016) studied the sensitivity of precipitation to doubling
140 droplet concentration, halving raindrop evaporation, and increasing initial cloud droplet
141 size. This study focuses on different parameterizations of autoconversion, accretion,
142 and entrainment-mixing. The simulations are compared against the precipitation dataset
143 that Ma *et al.* (2018) derived from sparse gauge observations and multiple satellite
144 precipitation datasets, including Tropical Rainfall Measuring Mission (TRMM)

145 Multisatellite Precipitation Analysis (TMPA) 3B42RT and 3B42V7 (*Huffman et al.*,
146 2007), Climate Prediction Center MORPHing technique (CMORPH) (*Joyce et al.*,
147 2004) and Precipitation Estimation from Remotely Sensed Information using Artificial
148 Neural Networks-Climate Data Record (PERSIANN-CDR) (*Ashouri et al.*, 2015). This
149 rain gauge dataset developed by *Ma et al.* (2018) is more accurate than individual
150 gauges for complex terrains such as the TP region. This dataset also has higher spatial
151 (0.1°) and temporal (1 h) resolution than TRMM, which is usually used in this region
152 (*Fu et al.*, 2007; *Yin et al.*, 2008; *Maussion et al.*, 2011; *Xu et al.*, 2012; *Qie et al.*, 2014).

153

154 **2.2 Model and experiment description**

155 The WRF model version 3.8.1 is used to simulate this typical summer TP
156 precipitation event. The WRF model is a next-generation mesoscale numerical weather
157 prediction system designed for both atmospheric research and operational forecasting
158 applications. Here, WRF is used as a cloud-resolving model with 1 km horizontal grid
159 spacing for the innermost domain (referred to as domain 03) with $276 \times 276 \times 45$ grid
160 points, which covers most of the plateau center; the spatial resolutions for the two outer
161 domains (01 and 02) are 25 km and 5 km with $200 \times 200 \times 45$ and $176 \times 176 \times 45$ grid
162 points, respectively (Figure 1). Initial and boundary conditions are provided by the
163 National Center for Environmental Prediction Final operational global analysis data
164 with 1° spatial and 6 h temporal resolution. The simulation starts at 1200 UTC 21 July
165 and ends at 0000 UTC 24 July, with a total of 60 h integration time. We focus on the

166 results of the last 48 h from domain 02 and domain 03 with a 30-minute interval.

167 The microphysics scheme used in the control run is the Morrison double-moment
168 scheme (Morrison and Grabowski, 2008). Note that this bulk scheme is different from
169 the default version released in the WRF model with a fixed cloud droplet number
170 concentration (N_c) (e.g. $N_c = 250 \text{ cm}^{-3}$). This version can predict the number
171 concentration and mass mixing ratios of cloud droplets (N_c, q_c), raindrops (N_r, q_r), ice
172 crystals (N_i, q_i), snow particles (N_s, q_s), and graupel particles (N_g, q_g) followed Morrison
173 *et al.* (2005). The main liquid-phase conversion processes, i.e. autoconversion rate (A_u ;
174 kg/kg/s) and accretion rate (A_c ; kg/kg/s), are both based on *Khairoutdinov and Kogan*
175 (2000), further referred to as the KK00 schemes:

$$176 \quad A_u = 1350 \times q_c^{2.47} (N_c \times 10^{-6} \times \rho_a)^{-1.79}, \quad (1)$$

$$177 \quad A_c = 67 \times (q_c q_r)^{1.15}, \quad (2)$$

178 where ρ_a is the air density.

179 To explore the influence of liquid-phase cloud microphysical processes in mixed-
180 phase clouds, we implement several different expressions for autoconversion, accretion,
181 and entrainment-mixing into the Morrison scheme, and examine the model sensitivity.
182 In addition to the default KK00 schemes, three commonly-used autoconversion
183 schemes are employed and referred to as Be68, Bh94, and LD04 for convenience,
184 respectively:

185 1) Be68:

$$186 \quad A_u = \frac{3.5 \times 10^{-2} q_c^2}{0.12 + 1.0 \times 10^{-12} \frac{N_c}{q_c}}, \quad (3)$$

187 This is the default scheme in several global climate models, such as Model for
 188 Interdisciplinary Research on Climate version 5 (MIROC5; *Michibata and Takemura,*
 189 2015; *Jing and Suzuki,* 2018).

190 2) Bh94:

$$191 \quad A_u = 6.0 \times 10^{28} n^{-1.7} (q_c \times 10^{-3})^{4.7} (N_c \times 10^{-6})^{-3.3}, \quad (4)$$

192 where n is set to 10 in Eq. 4, which is related to the width of cloud droplet size
 193 distribution (*Beheng,* 1994).

194 3) LD04:

$$195 \quad A_u = P_0 T, \quad (5a)$$

$$196 \quad P_0 = 1.1 \times 10^{13} \left[\frac{(1+3\varepsilon^2)(1+4\varepsilon^2)(1+5\varepsilon^2)}{(1+\varepsilon^2)(1+2\varepsilon^2)} \frac{q_c^3}{N_c} \right], \quad (5b)$$

$$197 \quad T = \frac{1}{2} (x_c^2 + 2x_c + 2)(1 + x_c) e^{-2x_c}, \quad (5c)$$

$$198 \quad x_c = 9.7 \times 10^{-14} N_c^{3/2} q_c^{-2}. \quad (5d)$$

199 LD04 derived by *Liu and Daum* (2004) and *Liu* (2005) considers relative dispersion ε
 200 (the ratio of the standard deviation to the mean radius) in addition to droplet
 201 concentration and liquid water mixing ratio. This scheme was implemented into the
 202 WRF double-moment schemes (*Xie and Liu,* 2011; *Xie et al.,* 2013). P_0 and T
 203 represent the rate function and threshold function, respectively; x_c is the normalized
 204 critical mass and can be written as a function of N_c and q_c (*Liu et al.,* 2005); ε is set to
 205 0.4 as the average value based on *Zhao et al.* (2006) and *Wang et al.* (2019a).

206 Considering that most accretion schemes only consider mass mixing ratios of
 207 cloud droplets and raindrops (i.e. q_c and q_r) (e.g. *Beheng,* 1994; *Khairoutdinov and*

208 *Kogan, 2000; Kogan, 2013*), a parameterization that relates the accretion process to
 209 liquid droplet number concentration and size is adopted from *Cohard and Pinty (2000)*,
 210 named as CP2k:

$$211 \quad A_c = \frac{\pi}{6} \rho_W \rho_a K_1 \frac{N_c N_r}{\lambda_c^3} \left(\frac{A_1}{\lambda_c^3} + \frac{B_1}{\lambda_r^3} \right),$$

212 *if* $R_r \geq 50 \mu m$, and (6a)

$$213 \quad A_c = \frac{\pi}{6} \rho_W \rho_a K_2 \frac{N_c N_r}{\lambda_c^3} \left(\frac{A_2}{\lambda_c^6} + \frac{B_2}{\lambda_r^6} \right),$$

214 *if* $R_r < 50 \mu m$, (6b)

215 where ρ_W is the water density; R_r is the raindrop radius; K_1 and K_2 are empirical
 216 constants; the subscripts c and r denote cloud droplets and raindrops, respectively; A_1 ,
 217 A_2 , B_1 , and B_2 are functions related to the two dispersion parameters of the modified
 218 Gamma size distribution (*Cohard and Pinty, 2000*) and their expressions are given in
 219 Appendix B; λ is the slope parameter and is derived from the dispersion parameter,
 220 number concentration and mixing ratio of the species (see *Morrison et al., 2005*). Given
 221 the specified dispersion parameters for raindrops, $\lambda_r = (\pi \rho_W N_r / q_r)^{1/3}$ which is
 222 inversely proportional to the mean volume radius of the raindrops. Another accretion
 223 scheme (*Ko13, Kogan, 2013*) is also tested:

$$224 \quad A_c = 8.53 \times q_c^{1.05} q_r^{0.98}, \quad (7)$$

225 A single parameter α is used to represent the effect of entrainment-mixing process
 226 in this microphysical scheme (*Morrison and Grabowski, 2008; Lu et al., 2013*):

$$227 \quad N_c = N_{c0} \left(\frac{q_c}{q_{c0}} \right)^\alpha, \quad (8)$$

228 where the N_c and N_{c0} are the number concentrations of cloud water droplets after and

229 before the evaporation process, respectively; q_c and q_{c0} represent the corresponding
 230 mixing ratios, respectively. It is noteworthy that q_c is mainly determined by q_{c0} , relative
 231 humidity, air pressure, and temperature when new saturation is achieved after
 232 evaporation. The parameter α can be set to any value between 0 and 1 corresponding to
 233 a different degree of the subgrid-scale mixing homogeneity. When $\alpha = 0$, homogeneous
 234 mixing is assumed (the control run). On the contrary, when $\alpha = 1$, extremely
 235 inhomogeneous mixing is assumed (the INHOMO run).

236 In total, we have 7 simulations: the control run with the KK00 schemes for
 237 autoconversion and accretion, and homogeneous mixing, and sensitivity tests with three
 238 autoconversion schemes (Be68, Bh94, and LD04), two accretion schemes (CP2k and
 239 Ko13), and one entrainment-mixing scheme (INHOMO). The case names and
 240 corresponding formulations are summarized in Table 1.

241

242 **2.3 Calculations of microphysical/radiative properties**

243 The liquid cloud water path (LCWP) is calculated by

$$244 \quad \text{LCWP} = \int_0^H \rho_a q_c(z) dz, \quad (9)$$

245 where $q_c(z)$ is the cloud water mixing ratio at each height (z). The equation for cloud
 246 optical depth (τ) is:

$$247 \quad \tau = \frac{3}{2} \frac{1}{\rho_w} \int_0^H \frac{\rho_a q_c(z)}{r_e(z)} dz, \quad (10)$$

248 where $r_e(z)$ is the effective radius of cloud droplets at each height (z); the extinction
 249 efficiency is assumed to equal to 2 (appropriate at visible wavelengths) (*Grabowski,*

250 2006); H is the cloud top height. With equations (9) and (10), the column mean effective
251 radius (\bar{r}_e) is given by

$$252 \quad \bar{r}_e = \frac{3 LCWP}{2 \rho_w \tau}, \quad (11)$$

253 Note that only the cloud data in the grid boxes with hydrometeor mixing ratios larger
254 than 0.01 g/kg are included.

255

256 **3. Case study Analysis**

257 **3.1 Control run**

258 **3.1.1 Precipitation from the control run and observations**

259 The 48 h accumulated precipitation from 0000 UTC 22 July to 0000 UTC 24 July
260 2014 from the control run over domain 02 and domain 03 are averaged to the resolution
261 of 0.1° to compare with observations (Figure 2). The results from domain 02 indicate
262 that the control run can reproduce the primary rainband. The observed precipitation in
263 most regions is less than 50 mm and the maximum value is approximately 80 mm.
264 Although the control run is spatially consistent with the observations, the maximum
265 simulated precipitation is about 200 mm, largely exceeding the observed value. Similar
266 biases were reported in *Xu et al.* (2012) and *Gao et al.* (2016). For domain 03, when
267 the simulated precipitation is averaged to 0.1° , there are only about 27×27 data points;
268 this data volume is insufficient to compare the spatial distribution of precipitation
269 between simulations and observations. This could explain the spatial precipitation bias
270 shown in Figures 2c and 2d. Besides spatial comparison, Figures 3a and 3b show the

271 temporal evolutions of area-averaged hourly precipitation rate from the observation and
272 the control run over domain 02 and domain 03, respectively. The black solid lines
273 denote the observations. The simulations of both domains temporally correlate well
274 with observations, but the domain 03 is clearly closer to the observations in terms of
275 precipitation rate. The observations for domain 03 show that there are two peaks of
276 precipitation in the local afternoon (UTC + 6 h). The first precipitation event starts from
277 0400 UTC and ends at 1800 UTC with the maximum precipitation rate of 1.0 mm/h
278 attained at 0900 UTC. The other precipitation peak is weak with a maximum
279 precipitation rate of only about 0.4 mm/h. The time of the peaks in the simulations is
280 about 2 hours later than that in the observations, which was also reported in *Gao et al.*
281 (2018).

282 Generally speaking, the control run captures the main features of the precipitation
283 evolution (the peaks and the trends). However, compared with the observations of 48 h
284 accumulated precipitation over the corresponding areas, the control run overpredicts
285 precipitation by 51.5% in domain 02 and by 20.8% in domain 03.

286

287 **3.1.2 Microphysical processes in the control run**

288 To examine the origin of the precipitation biases discussed above, a more in-depth
289 analysis of the microphysics is performed for both domains 02 and 03. For domain 02,
290 considering that the altitude of the southeastern corner is lower than the other regions,
291 liquid-phase precipitation is expected to be stronger. Therefore, domain 02 is divided

292 into two parts: the southeastern corner and the other regions. For domain 03, the two
293 precipitation peak periods are studied separately.

294 Figure 4 shows the mean vertical profiles of five types of hydrometeors and their
295 primary microphysical processes for the two separate regions over domain 02 and the
296 two precipitation peaks (5 hours) over domain 03, respectively. For domain 02, mixing
297 ratios of ice-phase hydrometeors (ice, snow, and graupel) and rates of microphysical
298 processes (RIM-s, RIM-g, MELT) over the southeastern corner (Figures 4c and d) are
299 generally equivalent to or smaller than those over the other regions (Figures 4a and b).
300 Mixing ratios of liquid-phase hydrometeors (cloud and rain) and microphysical
301 processes (ACCR-r, AUTO-r) are larger over the southeastern corner than those over
302 the other regions. As mentioned above, liquid droplets will grow more favorably over
303 the southeastern corner because of its lower terrain. For domain 03, mixing ratios of
304 ice-phase hydrometeors (ice, snow, and graupel) and rates of microphysical processes
305 (EVAP-r, ACCR-s, RIM-s, RIM-g, MELT) are smaller during the second peak period
306 (Figures 4g and h) than those during the first peak (Figures 4e and f). On the other hand,
307 accretion of cloud droplets by rain (ACCR-r) is larger for the second peak than for the
308 first one, while melting still dominates. By calculating the vertical accumulated
309 conversions of liquid-phase processes (ACCR-r and AUTO-r) and ice-phase processes
310 to raindrops, the contributions of ACCR-r and AUTO-r are 32.86%, 65.20%, 27.03%,
311 and 35.41% for other regions in domain 02 except southeastern corner, the southeastern
312 corner in domain 02, and two precipitation peaks in domain 03, respectively. Therefore,

313 the liquid-phase processes over the southeastern corner in domain 02 and the second
314 precipitation peak in domain 03 are more important than those over the other regions
315 in domain 02 and the first precipitation peak in domain 03, respectively. However, this
316 happens for different reasons. While ice phase processes are equally important across
317 the entire domain 02, the higher temperature in the lower southeastern corner allows
318 for more liquid-phase precipitation. In domain 03, however, the second peak is clearly
319 associated with smaller ice-related conversion rates.

320

321 **3.2 Sensitivity of precipitation overprediction to different liquid-phase processes**

322 Precipitation, microphysical properties, and their related processes from the
323 sensitivity simulations are discussed in this section, including Be68, Bh94, LD04, CP2k,
324 Ko13, and INHOMO. The effects of these schemes on precipitation overprediction are
325 examined in detail.

326

327 **3.2.1 Evaluation of surface precipitation**

328 The results for precipitation from the sensitivity tests are shown in Figures 5 and
329 6. All sensitivity tests reproduce a similar location, trend, and precipitation rate,
330 compared to the control run, except the CP2k experiment. CP2k has distinctly weaker
331 precipitation than the other simulations especially over the southeastern corner in
332 domain 02 and during the second precipitation peak period in domain 03. CP2k
333 overestimates precipitation by 30.2% in domain 02, which is an improvement compared

334 to the control and other sensitivity tests (48.8%-52.5%); in domain 03, the
 335 overprediction in the CP2k is only 10.9%, also much smaller than the 15.1% in
 336 INHOMO and 20.8%-26.9% in the control and other sensitivity tests. Some previous
 337 studies found large variation of precipitation by using different autoconversion schemes
 338 (*Li et al.*, 2008a; *Wang et al.*, 2013), while other studies showed that surface
 339 precipitation was insensitive to the choice of autoconversion schemes (*Morrison and*
 340 *Grabowski*, 2007; *Michibata and Takemura*, 2015). It seems that such a sensitivity may
 341 vary by cloud regimes and even case by case. The limited effects of different
 342 autoconversion schemes on the surface precipitation rate in this study could be related
 343 to the dominance of melting and accretion in raindrop formation, and large precipitation
 344 amount

345 The Heidke skill score (HSS) is used to further quantitatively evaluate the
 346 simulations with different schemes:

$$347 \quad \text{HSS} = \frac{2(ad - bc)}{(a + c)(c + d) + (a + b)(b + d)}, \quad (12)$$

348 where the four elements a - d for HSS, representing the numbers of “hits”, “false alarms”,
 349 “misses” and “correct negatives”, respectively, are calculated from a contingency table
 350 (Table 2). HHS can not only judge well-simulated events (both hits and correct
 351 negatives, element a and d) but also account for the erroneous forecast (b and c)
 352 (*Barnston*, 1992). A higher HSS (0-1) represents better skill. As shown in Table 2, p_t is
 353 the threshold value and is set to be 2 mm covering most of the observed and simulated
 354 precipitation area, p_s and p_o are the values from simulations and observations,

355 respectively.

356 The elements a - d and HSS for all sensitivity tests over domains 02 and 03 are
357 shown in Table 3. All the cases in domain 02 have the HSS scores exceeding 0.4 and
358 are close to each other except for CP2k. The impacts of changing autoconversion
359 schemes and mixing mechanisms on HSS are limited. The CP2k accretion scheme,
360 however, has significantly higher HSS than other cases, particularly due to its high
361 value of d , the “correct negatives” mainly over the southeastern region for domain 02.
362 The high HSS scores in CP2k indicate that changing the accretion scheme is a possible
363 way to improve the much-overestimated precipitation in simulations over this region.
364 The HSS scores of all simulations for domain 03 are small because there are too few
365 data points for evaluation, as mentioned above; slight changes in any of the four factors
366 can cause a large difference in the final scores. However, the CP2k case still has the
367 highest HSS of 0.152, much larger than the maximum and mean HSS of other cases,
368 0.110 and 0.076, respectively.

369

370 **3.2.2 Impact of liquid-phase parameterization on cloud properties**

371 Table 4 summarizes the microphysical properties for all the simulations, including
372 LCWP, \bar{r}_e and N_c over domains 02 and 03, respectively. It is noteworthy that the CP2k
373 scheme has the largest effect on LCWP and \bar{r}_e among all the sensitivity tests.
374 Compared to the control run, differences of the CP2k case over domain 02 (03) are
375 +64.6% (+51.0%) in LCWP and +7.9% (+5.6%) in \bar{r}_e while the other accretion

376 sensitivity test, using Ko13, is much closer to the control run. The reasons will be
377 analyzed in Section 3.3.2. Cloud observational data from Clouds and the Earth's
378 Radiant Energy System (CERES) project with 1 h time resolution and 1° spatial
379 resolution are also provided in Table 4. Among all the simulations, the CP2k case has
380 the results of LCWP and $\bar{\tau}_e$ closest to the observations.

381 The difference between all autoconversion sensitivity tests and the control run for
382 LCWP and $\bar{\tau}_e$ are, respectively, from -13.7% to 10.6% and -1.9% to 2.3% over domain
383 02, and from -11.1% to 13.9% and -1.2% to 3.5% over domain 03. The wide ranges are
384 mainly caused by one order of magnitude difference of A_u amongst the different
385 sensitivity tests (Figures 7a and b). However, the magnitude of the difference is much
386 smaller than that in typical marine boundary layer clouds (*Wood, 2005b*), because of
387 the thinner liquid-phase layer and the involvement of ice/mixed-phase processes over
388 the TP. The sign of the difference between the schemes is consistent with previous
389 studies, e.g., Be68 and LD04 have larger A_u than KK00 (Figures 7a and b) (*Lee and*
390 *Baik, 2017*).

391 For the entrainment-mixing process, the INHOMO experiment has the largest
392 effect on N_c among all the sensitivity tests. Even so, there is only a modest reduction of
393 only 2.6 (4.9) / cm^3 compared to the control run, resulting in 0.9% (1.5%) larger $\bar{\tau}_e$ over
394 domain 02 (03). It seems that the influence of INHOMO in domain 03 is greater than
395 that in domain 02 since the relevant scales involved in the entrainment-mixing process
396 are usually small and domain 03 has a higher resolution than domain 02. Such a

397 variation of \bar{r}_e over domain 03 is comparable with that in all the autoconversion
398 schemes and Ko13. The variation of LCWP is smaller than that in the liquid conversion
399 process. Sensitivity tests of all autoconversion and accretion schemes in Table 4 are
400 also conducted assuming different mixing mechanisms (See supplement for details).
401 The effects are also small, similar to several previous studies using double-moment
402 microphysics schemes (*Hill et al.*, 2009; *Grabowski and Morrison*, 2011; *Slawinska et*
403 *al.*, 2012). One important reason is that the relative humidity in entrained air is high
404 (*Slawinska et al.*, 2012; *Hoffmann and Feingold*, 2019).

405

406 **3.3 Reasons for improvements of precipitation overprediction in CP2k**

407 As mentioned before, CP2k reduces the precipitation overprediction more
408 significantly than other sensitivity tests. The reasons are discussed in this section.

409

410 **3.3.1 Detailed microphysical processes in CP2k**

411 CP2k experiences an A_c rate that is one to two orders of magnitude smaller than
412 in the control run and other sensitivity tests (Figures 7c and d). The reason for why A_c
413 in the control run and other sensitivity tests is so close is that the KK00 and the Ko13
414 schemes have similar functions of rain and cloud water content (Eqs. 2 and 7) and
415 similar variation trends in Figure 9 (which is analyzed in Section 3.3.2 in detail). In
416 each case, larger A_u enhances A_c by providing more rain drops. Therefore, the trend
417 of A_c corresponds well to that of A_u . The result between different cases is different

418 from that in each case. Compared with the control run, A_c in CP2k is smaller, and thus
419 fewer cloud droplets are collected by raindrops; these surviving cloud droplets are then
420 available for autoconversion, which leads to the larger A_u in CP2k (e.g. *Gettelman et*
421 *al.*, 2013; *Posselt and Lohmann*, 2008). As shown in Figures 7a and b, A_u in CP2k is
422 much larger than that in the control run; the difference is close to the value from
423 applying different autoconversion schemes. Therefore, CP2k has the lowest ratio
424 A_c/A_u with the mean value of 2.88 (2.81) over domain 02 (03) mainly because of small
425 A_c . Bh94 has the largest ratio A_c/A_u with a mean value of 151.24 (144.60) over
426 domain 02 (03). Indeed, Bh94 exhibits the smallest A_u (Figures 7e and f) of all
427 schemes tested here. A_c/A_u of all schemes is in the range of 0.1-296.3, consistent with
428 previous studies (*Gettelman et al.*, 2013; *Lee and Baik*, 2017; *Michibata and Takemura*,
429 2015; *Seifert and Onishi*, 2016; *Jiang et al.*, 2010). In domain 03, A_c/A_u larger than 1
430 usually corresponds to larger precipitation intensity; A_c/A_u smaller than 1 usually
431 corresponds to smaller precipitation at the start or the end of precipitation events. This
432 correspondence is consistent with the arguments as to accretion-dominated and
433 autoconversion-dominated regimes (*Jiang et al.*, 2010; *Wood et al.*, 2009; *Michibata*
434 *and Takemura*, 2015). In domain 02, most of A_c/A_u is larger than 1; some A_c/A_u
435 values are smaller than 1 but still with strong precipitation likely caused by the
436 influence of ice/mixed-phase processes.

437 Combining two dominant liquid-phase rain formation processes (autoconversion
438 and accretion), less cloud water is depleted in CP2k; as a result, the mean value of

439 LCWP is over 50.0% larger than that of the control run, as shown in Table 4. Figure 8
440 shows the vertical profiles of the mean differences of the dominant conversion process
441 rates between CP2k and the control run (CP2k-Control) over the two regions in domain
442 02 and during the two precipitation peak periods in domain 03. Similar to Figure 7,
443 CP2k has a much smaller A_c and larger A_u . Despite the larger A_u , many cloud
444 droplets are suspended above the 0 °C isotherm, beneficial for riming of cloud droplets
445 onto snow or graupel particles (RIM-s + RIM-g). Figure S1 in the supplementary
446 material shows the microphysical processes conversion rates in CP2k with riming
447 minus those without riming. Riming suppresses the liquid-phase rain formation
448 processes through reducing A_c , but enhances ice/mixed-phase rain formation processes
449 through increasing melting rate. The sensitivity of warm/cold rain formation to riming
450 ultimately trickles down to uncertainties in the simulation of surface precipitation.

451 Note that the smaller melting rate near 6 - 6.5 km in CP2k over domain 03 is
452 because of the lower melting level in CP2k than in the control run. Given the larger
453 water content, CP2k also has a larger optical depth τ (14.3) than the control run (11.1),
454 which means more solar radiation is reflected to the upper atmosphere and less short-
455 wave radiation reaches the ground (219.6 W/m² in CP2k vs 226.5 W/m² in the control
456 run). Qualitatively, such a difference in radiation could be one reason responsible for a
457 lower temperature in CP2k in the low atmosphere than in the control run, other things
458 being equal (e.g., latent heating release). Therefore, the melting level is lower in CP2k.

459 The source of surface precipitation includes both the liquid-phase (mainly ACCR-

460 r) and the ice/mixed-phase. During the first precipitation peak period in domain 03,
461 despite the smaller A_c in CP2k than that in the control run, more riming leads to more
462 melting. The combination of weaker accretion and stronger melting in CP2k offset each
463 other, and hence the precipitation from CP2k and the control run is very close in this
464 period (Figure 6b). A similar chain of events also occurs in domain 02 except for the
465 southeastern corner (Figures 2b and 5d). However, in the control run, due to relatively
466 low concentration of ice particles during the second peak period in domain 03, the
467 liquid-phase processes, in particular accretion, become relatively more important
468 (Figure 4h); for the southeastern corner of domain 02, the large mixing ratio of cloud
469 droplets even causes A_c to exceed the melting rate (Figure 4d). Surface precipitation
470 is overestimated in the control run compared with the observations, as discussed in
471 Section 3.2.1. In CP2k, the accretion is suppressed which appears to alleviate the
472 overestimation of precipitation. Therefore, the total surface precipitation in CP2k is
473 smaller than that in the control run over the southeastern corner in domain 02 and during
474 the second peak period in domain 03, which is closer to observations.

475

476 **3.3.2 Theoretical analysis of the CP2k parameterization**

477 The large differences in cloud microphysics and precipitation between CP2k and
478 other cases can be explained based on the different equations for autoconversion and
479 accretion (Eqs. 2, 6 and 7). The different equations for the autoconversion and accretion
480 can be separated into two basic methods as mentioned in *Wood* (2005b): the first one

481 integrates the stochastic collection equation for a wide range of drop size distributions
482 and then uses a simple power-law fit, such as the KK00 scheme in the control run. The
483 second method simplifies the collection kernel and parameterizes the autoconversion
484 and accretion processes, such as the parametrization of the A_u in LD04 and A_c in
485 CP2k. Autoconversion schemes commonly use one of these basic methods. However,
486 the accretion schemes used in most of the microphysical schemes are based on the first
487 method, and previous studies focus on comparing accretion schemes using this method
488 (*Wood, 2005b; Hill et al., 2015*). As shown above and also below, the CP2k accretion
489 parameterization is unique and appears superior to other parameterizations, but this
490 parameterization is only used in a few microphysics schemes (e.g. WDM6 scheme in
491 WRF, *Lim and Hong, 2010*).

492 Figure 9 compares the A_c calculated as a function of raindrop radius for all the
493 accretion schemes under the conditions of $q_c = 1$ g/kg, $R_c = 10$ μm , $N_r = 4000$ /m³. It is
494 obvious that the three schemes result in different relationships for the A_c . Considering
495 the power-law form in the formula from the first method, i.e., the KK00 scheme in the
496 control run and the Ko13 scheme, A_c is linearly related to raindrop radius in the
497 logarithmic space. However, CP2k has an inflection point at 50 μm due to the piecewise
498 function in Eq. 6. Under the condition of adequate cloud water, the accretion process in
499 the KK00 or the Ko13 scheme only depends on the rain water mixing ratio. However,
500 in CP2k, if the raindrop radius is less than 50 μm , the A_c is very small. As shown in
501 Figure 9, the A_c in the KK00 or the Ko13 scheme is always larger than that in CP2k

502 when the raindrop radius is smaller than 2000 μm . The difference between CP2k and
503 the other two schemes increases with decreasing raindrop radius; especially when the
504 raindrop radius is smaller than 50 μm , with the maximum difference being more than
505 two orders of magnitude. Therefore, the probability density distributions (PDFs) of
506 raindrop radius are important for the difference between different accretion schemes.

507 Figure 10 shows the PDFs of raindrop radius used in the accretion process in the
508 three schemes. All raindrops are smaller than $10^3 \mu\text{m}$. The PDFs have peaks of ~ 30 ,
509 ~ 30 , and $\sim 25 \mu\text{m}$ in the control run, Ko13, and CP2k, respectively, and the cumulative
510 PDF shows that the raindrops with radius smaller than 50 μm have frequencies of 58.8%,
511 53.8%, and 46.0%, respectively. The drop size distributions from both aircraft
512 observations and bin models also confirm that a large proportion of liquid droplets have
513 radii larger than 25 μm but smaller than 50 μm (*Wood, 2005a; Morrison and Grabowski,*
514 *2007*). Such a large percentage of small raindrops makes the A_c and precipitation in
515 CP2k quite different from that in other schemes (Figure 9). Furthermore, there is a
516 positive feedback mechanism, since accretion increases q_r and A_c is positively
517 correlated with q_r . The overestimation of the A_c in KK00 or Ko13 hence feeds back on
518 itself. This is the reason why the precipitation and accretion rate differences between
519 KK00 and CP2k are so large over the southeastern corner in domain 02 and during the
520 second peak period in domain 03.

521 Previous studies have shown that to initiate liquid phase precipitation, the cloud
522 effective radius needs to reach about 14 μm (*Rosenfeld et al., 2019*). A closer look at

523 the cloud droplet sizes is hence informative to understand the differences in
524 precipitation behavior between CP2k and the other experiments. Figure 11 shows the
525 liquid-phase precipitation rate as a function of cloud droplet effective radius. The
526 liquid-phase precipitation rate is estimated as the product of total precipitation and the
527 ratio of liquid-phase process rates (autoconversion + accretion) and ice/mixed-phase
528 process rates (melting from snow + graupel). The liquid-phase precipitation rate
529 exceeds 2 mm/day when the cloud effective radius is 9 μm in the control run and Ko13.
530 In CP2k, it is not until the cloud effective radius reaches about 15 μm , that the
531 precipitation rate exceeds 2 mm/day. The contribution from autoconversion is close to
532 0 in the control run, which could be due to the consumption of cloud droplets by
533 accretion after droplets reach 9 μm . The value of 9 μm , is much smaller than 14 μm
534 needed to initiate liquid-phase precipitation, often suggested by observational studies
535 (*Rosenfeld et al.*, 2019). On the contrary, there is a significant increase in liquid-phase
536 precipitation rate from the autoconversion and accretion processes in CP2k at 15 μm .
537 Although A_u in CP2k is larger than that in other schemes, A_c ultimately determines
538 the liquid-phase precipitation rate, which has been discussed in many previous studies
539 (e.g., *Jiang et al.*, 2010; *Wood et al.*, 2009; *Michibata and Takemura*, 2015; *Gettelman*
540 *et al.*, 2015). The liquid-phase precipitation is suppressed by a weak A_c . Furthermore,
541 large A_u in CP2k can increase q_r but decrease q_c , which may enhance or suppress A_c
542 (*Posselt and Lohmann*, 2008). In other schemes, the accretion process is triggered to a
543 considerable amount with small liquid drops due to the overestimation of A_c when

544 confined to small drops. Therefore, the improvement in CP2k surface precipitation
545 compared to the control, appears to occur for the right reasons.

546

547 **4. Long-term analysis**

548 While the analysis of the single case study has allowed for an in-depth analysis, it
549 remains to be verified whether this case study is representative of the general behavior
550 of the model. As pointed out by *White et al.*, 2017), it is hard to be conclusive that one
551 scheme is better than others based on a few cases. Hence, one-month simulations are
552 performed from 0000 UTC 21 July to 0000 UTC 21 August 2014 with the same
553 domains in Figure 1, using the three accretion schemes (the control run, CP2k, and
554 Ko13). Only the results starting from 0000 UTC 22 July are analyzed. The horizontal
555 resolutions for domains 01, 02 and 03 are 30, 10 and 3.3 km, respectively; except for
556 the resolutions and simulation time, all other settings are the same as those in the two-
557 days simulations in Section 3.

558 Figure 12 shows the temporal evolution of the area-averaged daily precipitation
559 rate in domains 02 and 03 from the three accretion simulations and the observations.
560 Compared with the observed precipitation, the control run significantly overestimates
561 precipitation for most days, especially in domain 02. The average precipitation rate in
562 the observation, the control run, Ko13, and CP2k are, respectively, 1.56, 2.46, 2.49, and
563 2.17 mm/day over domain 02, and 4.54, 5.80, 5.87, and 5.17 mm/day over domain 03.
564 The results of Ko13 are very close to those in the control run, while CP2k significantly

565 reduces precipitation overprediction with p -values of student's t-test less than 0.01 for
566 both domain 02 and domain 03. Table 5 shows that CP2k has higher HSS scores than
567 the control run and Ko13 over both domains 02 and 03. Therefore, the effects of CP2k
568 on reducing precipitation overprediction are not limited to one specific case but appear
569 to be a plausible way to improve precipitation overprediction, at least of the Tibetan
570 Plateau.

571 The one-month simulations provide the opportunity to investigate the response of
572 the PDF of the surface precipitation to the changes of accretion schemes over the TP
573 region. The PDFs are based on the hourly precipitation rate from 0000 UTC 21 July to
574 0000 UTC 21 August 2014 with the three accretion schemes (the control run, CP2k,
575 and Ko13). As expected, Figure 13 shows that CP2k has more weak precipitation (<
576 ~ 0.2 mm/h) over both domains 02 and 03 than the control run and Ko13, corresponding
577 to the smaller total surface precipitation in CP2k. The results indicate that the PDF of
578 the surface precipitation is subject to the changes in the microphysical schemes over
579 the TP region. Furthermore, considering the significant climate effects of the TP region,
580 it is interesting to see whether microphysical schemes have significant effects on the
581 historical trend of precipitation intensity distribution with simulations over years in the
582 future research using the method in *Wang et al.* (2016).

583

584 **5. Sensitivity to horizontal resolution**

585 Different resolutions in the two simulations (case study from 22 to 23 July 2014

586 and long-term one-month simulation from 22 July to 21 August 2014) provide a good
587 opportunity to examine the effects of resolution on precipitation overprediction. The
588 area-averaged precipitation rate during the first two days (from 22 to 23 July) from the
589 one-month simulation is 0.36 mm/h in domain 03 with the resolution of 3.3 km (Figure
590 12b), which is larger than the 0.29 mm/h with the resolution of 1 km and the 0.24 mm/h
591 from the observations (Figure 6b). Similarly, the first two-days area-averaged
592 precipitation rate is 0.41 mm/h in domain 02 with the resolution of 10 km (Figure 12a),
593 larger than 0.32 mm/h with the resolution of 5 km and 0.21 mm/h from the observations
594 (Figure 6a). Furthermore, comparison with the precipitation in domains 02 and 03 also
595 provides some hints on the effects of resolutions. For the one case study, domain 02
596 with the resolution of 5 km (Figure 6a) overpredicts 51.5% of precipitation compared
597 with observations, and the number for domain 03 with the resolution of 1 km is only
598 20.8% (Figure 6b). For the one-month study, domains 02 and 03 overpredict
599 precipitation by 57.7% and 27.8%, respectively (Figure 12). These results confirm that
600 the model grid size plays an important role in the overprediction of precipitation over
601 the TP.

602 *Sato et al.* (2008) showed that a higher resolution simulation was more accurate in
603 reproducing the diurnal variation of precipitation, with precipitation rate more
604 consistent with observations. They claimed that higher resolution (< 7 km) may resolve
605 the convection initially occurred by the surface heating and consequently conduct a
606 proper simulation of the precipitation. *Xu et al.* (2012) found that the WRF simulations

607 at a resolution of 3 km could reproduce the timing of precipitation events but the
608 intensities were doubled. The first two-days comparison in our study shows that, when
609 the horizontal resolution increases from 3.3 km to 1 km, the simulation of precipitation
610 intensity can be effectively improved without affecting the trends of precipitation. This
611 indicates that 1 km or even higher resolution is needed to accurately simulate the
612 precipitation over the TP, possibly because such high resolutions can better resolve the
613 orography of this region.

614

615 **6. Summary and conclusions**

616 In this paper, a typical summer plateau precipitation event over the Tibetan Plateau
617 is simulated using the WRFv3.8.1 model with the Morrison double-moment scheme.
618 The control run reproduces the primary spatial distribution and temporal evolution of
619 precipitation rate. However, precipitation is significantly overestimated. To understand
620 the role of liquid-phase microphysical processes in the overprediction of precipitation,
621 sensitivity tests are conducted by introducing three parameterized liquid-phase
622 processes into the Morrison double-moment scheme, including three autoconversion
623 parameterizations (Be68, Bh94, and LD04), two accretion parameterizations (CP2k and
624 Ko13), and one entrainment-mixing parameterization (INHOMO).

625 The precipitation overprediction is significantly reduced with the accretion
626 scheme from *Cohard and Pinty* (2000). The Heidke skill scores with CP2k also show
627 better results compared to other cases. Furthermore, each simulation is further divided

628 into two parts: one with dominant ice/mixed-phase processes, the other with dominant
629 liquid-phase processes. The simulations have the largest differences when the liquid-
630 phase processes dominate, and the improvement in the CP2k experiment is more
631 pronounced. When the ice/mixed-phase processes are important, all the simulations are
632 equivalent, including CP2k. There are several reasons for this behavior. The accretion
633 rate is smaller in the CP2k experiment than that in the control run, which suppresses
634 precipitation due to liquid-phase processes. Due to weaker accretion, more cloud
635 droplets remain suspended in the atmosphere and are available for riming onto snow
636 and graupel. Precipitation due to melting from snow and graupel is then enhanced. The
637 combination of the weaker accretion and stronger melting in CP2k offset each other.
638 That is the reason why the precipitation does not change much in CP2k when ice/mixed-
639 phase processes dominate. When the ice/mixed-phase processes are relatively weak, the
640 precipitation from the enhanced riming and melting processes cannot compensate for
641 the loss of precipitation due to the suppression of accretion. Therefore, the precipitation
642 rate is smaller in CP2k than in the control run.

643 To understand the physical reasons for the improved performance of CP2k, the
644 equations for parameterizing accretion rate in CP2k, KK00, and Ko13 are compared
645 directly. The accretion rate in CP2k is always smaller than in the KK00 or the Ko13
646 scheme when the raindrop radius is smaller than 2000 μm . Furthermore, the difference
647 increases with decreasing raindrop radius and can amount to more than two orders of
648 magnitude when the raindrop radius is smaller than 50 μm . The PDFs of raindrop radii

649 have their peaks around 30 μm . Around 50% of raindrops have radius less than 50 μm .
650 This is the reason why CP2k suppresses accretion and liquid-phase precipitation
651 compared to the other two schemes. Further insight into the reasons for different
652 behavior in CP2k compared to the other schemes is provided through the relation of
653 cloud droplet size and liquid phase precipitation rates. It is often claimed that, to initiate
654 liquid-phase precipitation, the cloud effective radius needs to reach 14 μm . When the
655 cloud effective radius is 9 μm in the control run and Ko13, the liquid-phase precipitation
656 rate already exceeds 2 mm/day, however; in CP2k, on the other hand, liquid-phase
657 precipitation does not start until the effective radius reaches about 15 μm , which is more
658 consistent with observations.

659 The results in terms of precipitation sensitivity were confirmed in a long-term one-
660 month simulation as well. The time series of daily precipitation rate indicates that the
661 reduction in precipitation bias using CP2k is generally valid. CP2k also has the highest
662 HSS scores. Hence, it is assumed that the CP2k scheme generally produces more
663 accurate simulations of precipitation, at least over the Tibetan Plateau. More studies are
664 needed to understand whether these findings are applicable to regions beyond the
665 Tibetan Plateau as well. Theoretically, accretion is significantly affected by cloud
666 droplet and raindrop sizes, and these sizes are related to number concentrations and
667 liquid water mixing ratios of cloud droplets and raindrops. Therefore, it may be more
668 convincing to simultaneously consider number concentrations and liquid water mixing
669 ratios in the future development of the accretion parameterizations, similar to CP2k.

670 We also confirm that higher resolution simulations reduce precipitation
671 overestimation compared to lower resolution simulations, as pointed out by previous
672 studies (e.g., *Sato et al.*, 2008, *Xu et al.*, 2012). For the same simulation domains with
673 different resolutions, the results in the high-resolution simulations are much closer to
674 the observations.

675 It is noteworthy that small impacts of changing entrainment-mixing mechanisms
676 and autoconversion schemes could be related to the cloud type in the Tibetan Plateau
677 area. More studies are needed to further examine the impacts of these processes and
678 accretion on cloud and precipitation under different conditions, with the ratio of
679 accretion rate to autoconversion rate (*Wood*, 2005b; *Gettelman et al.*, 2013; *Lee and*
680 *Baik*, 2017; *Michibata and Takemura*, 2015; *Seifert and Onishi*, 2016; *Jiang et al.*, 2010)
681 and the entrainment-mixing parameterizations (*Lu et al.*, 2013). Furthermore, although
682 our research shows the importance of the accretion process, it cannot be ignored that
683 the ice-phase processes are also important in this region. Therefore, it is necessary to
684 study the parameterizations of different ice-phase processes in the Tibetan Plateau area
685 in the future.

704

705 **Appendix A: Symbol List**

706 N_c : number concentration of cloud droplets

707 q_c : mixing ratio of cloud droplet

708 N_r : number concentration of raindrops

709 q_r : mixing ratio of raindrops

710 N_i : number concentration of ice crystals

711 q_i : mixing ratio of ice crystals

- 712 N_s : number concentration of snow particles
- 713 q_s : mixing ratio of snow particles
- 714 N_g : number concentration of graupel particles
- 715 q_g : mixing ratio of graupel particles
- 716 A_u : conversion rate of accretion process
- 717 A_c : conversion rate of autoconversion process
- 718 ρ_a : air density
- 719 ε : dispersion
- 720 ρ_w : water density
- 721 λ : slope parameter
- 722 N_{c0} : number concentration of cloud water droplets before evaporation process
- 723 q_{c0} : mixing ratio of cloud water droplets before evaporation process
- 724 p : the threshold value of precipitation in the Heidke skill score
- 725 p_s : value of precipitation from simulations in the Heidke skill score
- 726 p_o : value of precipitation from observation in the Heidke skill score
- 727 τ : cloud optical depth
- 728 \bar{r}_e : averaged effective radius of cloud water droplets
- 729 LCWP: liquid cloud water path
- 730 EVAP-r: evaporation of raindrops
- 731 ACCR-r: accretion of cloud liquid water by rain
- 732 AUTO-r: autoconversion from cloud droplets to raindrops

733 MELT: melting from snow or graupel particles to raindrops

734 AUTO-s: autoconversion of cloud ice to snow

735 ACCR-s: accretion of cloud ice by snow

736 RIM-s: accretion of cloud droplets by snow particle

737 RIM-g: accretion of cloud droplets by graupel particle

738

739 **Appendix B: Four Parameters in Equation (6)**

740 In Equation (6), A_1 , A_2 , B_1 , and B_2 are the functions related to two dispersion
741 parameters of the gamma size distribution given by:

742
$$A_1 = \frac{\Gamma(\nu_c + 6/\alpha_c)}{\Gamma(\nu_c)} \quad (\text{B1a})$$

743
$$B_1 = \frac{\Gamma(\nu_c + 3/\alpha_c)}{\Gamma(\nu_c)} \frac{\Gamma(\nu_r + 3/\alpha_r)}{\Gamma(\nu_r)} \quad (\text{B1b})$$

744
$$A_2 = \frac{\Gamma(\nu_c + 9/\alpha_c)}{\Gamma(\nu_c)} \quad (\text{B1c})$$

745
$$B_2 = \frac{\Gamma(\nu_c + 3/\alpha_c)}{\Gamma(\nu_c)} \frac{\Gamma(\nu_r + 6/\alpha_r)}{\Gamma(\nu_r)} \quad (\text{B1d})$$

746 where ν and α are the two dispersion parameters in normalized form of cloud–
747 raindrop size distributions $n(D) = N \frac{\alpha}{\Gamma(\nu)} \lambda^{\nu} D^{\alpha\nu-1} \exp[-(\lambda D)^{\alpha}]$; λ is the slope

748 parameter; D and N represent diameter and total number concentration, respectively.

749 Subscripts c and r in Eqs. (B1) represent cloud droplets and raindrops, respectively.

1076 **Caption List:**

1077 **Table 1.** Summary of case names and corresponding formulations for the seven
1078 experiments. The meaning of each symbol and references for each case can be found in
1079 the text.

1080 **Table 2.** Contingency table used to calculate the Heidke skill score (HSS). The elements
1081 $a-d$ represent the numbers of “hits”, “false alarms”, “misses” and “correct negatives”,
1082 respectively. p_t is the threshold value of precipitation in observation and simulations, p_s
1083 is the value from simulations and p_o is the value from observations.

1084 **Table 3.** The values of four elements $a-d$ and Heidke skill score (HSS) for all
1085 simulations over domain 02 and domain 03 (d02/d03) of the control run, Be68, Bh94,
1086 LD04 (different autoconversion schemes), CP2k, Ko13 (different accretion schemes)
1087 and INHOMO run (different mixing mechanism).

1088 **Table 4.** The area-averaged liquid cloud water path LCWP (g/m^2), mean effective
1089 radius \bar{r}_e (μm) and number concentration N_c ($/\text{cm}^3$) of cloud droplets over domains 02
1090 and 03 (d02/d03) of the control run, Be68, Bh94, LD04 (different autoconversion
1091 schemes), CP2k, Ko13 (different accretion schemes) and INHOMO run (different
1092 mixing mechanism). The observation results from Clouds and the Earth's Radiant
1093 Energy System (CERES) are also shown.

1094 **Table 5.** The values of four elements *a-d* and Heidke skill score (HSS) for three one-
1095 month simulations over domain 02 and domain 03 of the control run and CP2k, Ko13
1096 (different accretion schemes).

1097

1098 **Figure 1.** Geographic locations of the three domains used in the numerical simulation.
1099 The color bar represents the height (m) above the sea level.

1100 **Figure 2.** Spatial distributions of 48 h accumulated precipitation (mm) during 0000
1101 UTC 22 July to 0000 UTC 24 July 2014 from the observations and the control run over
1102 domain 02 (a, b) and domain 03 (c, d).

1103 **Figure 3.** Time series of area-averaged hourly precipitation rate (mm/h) during 0000
1104 UTC 22 July to 0000 UTC 24 July 2014 over (a) domain 02 and (b) domain 03 from
1105 the observations and the control run.

1106 **Figure 4.** Mean vertical profiles of mixing ratios (g/kg) of cloud droplets (q_c),
1107 raindrops(q_r), ice particles(q_i), snow particles (q_s), graupel particles(q_g) and their
1108 primary microphysical processes in the control run (a, b) averaged from 48 h over

1109 domain 02 except southeastern corner, (c, d)averaged from 48 h at southeastern corner
1110 over domain 02, averaged during two precipitation peaks (e, f) 0700-1200 UTC 22 July
1111 2014 and (g, h) 0700-1200 UTC 23 July 2014 over domain 03. The purple dot-dash
1112 lines denote the mean height of 0 °C isotherm.

1113 **Figure 5.** Spatial distributions of 48 h accumulated precipitation (mm) during 0000
1114 UTC 22 July to 0000 UTC 24 July 2014 from observations and all sensitivity
1115 simulations over (a-f) domain 02 and domain 03.

1116 **Figure 6.** Time series of area-averaged hourly precipitation rate (mm/h) during 0000
1117 UTC 22 July to 0000 UTC 24 July 2014 over (a) domain 02 and (b) domain 03 from
1118 the observations and all simulations.

1119 **Figure 7.** The time series of area-averaged autoconversion rate, accretion rate, and the
1120 ratio of accretion rate to autoconversion rate (A_c/A_u) over (a, c, e) domain 02 and (b, d,
1121 f) domain 03 for all simulations, respectively.

1122 **Figure 8.** Differences of mean vertical profiles of the dominated microphysical
1123 processes conversion rates between CP2k and the control run (CP2k-Control) from (a)
1124 domain 02 except southeastern corner, (b) the southeastern corner of domain 02, and
1125 during the two precipitation peak periods (c) 0700-1200 UTC 22 July and (d) 0700-
1126 1200 UTC 23 July over domain 03. The purple dot-dash lines denote the mean height
1127 of 0 °C isotherm.

1128 **Figure 9.** The accretion rate as a function of raindrop radius with fixed cloud mixing
1129 ratio $q_c = 1$ g/kg, the radius of cloud droplet $R_c = 10$ μm , number concentration of
1130 raindrops $N_r = 4000$ / m^3 for the three accretion schemes.

1131 **Figure 10.** Probability distribution function (PDF) and cumulative PDF of raindrop
1132 radius involved in the accretion process for (a) the control run, (b) CP2k, and (c) Ko13.
1133 The purple line denotes the radius of raindrop equal to 50 μm .

1134 **Figure 11.** Dependence of warm rain intensity on cloud effective radius from the
1135 control run and CP2k during 0000 UTC 22 July to 0000 UTC 24 July 2014 over domain
1136 03.

1137 **Figure 12.** Time series of area-averaged daily precipitation rate (mm/day) from 0000
1138 UTC 22 July to 0000 UTC 20 August 2014 over (a) domain 02 and (b) domain 03 in
1139 the observations and three accretion cases (the control run, CP2k and Ko13).

1140 **Figure 13.** Probability distribution function (PDF) of precipitation rate (mm/h) from
1141 0000 UTC 21 July to 0000 UTC 21 August 2014 over (a) domain 02 and (b) domain 03
1142 in the three accretion cases (the control run, CP2k and Ko13).

1143

1144

1145 Table 1. Summary of case names and corresponding formulations for the seven
 1146 experiments. The meaning of each symbol and references for each case can be found in
 1147 the text.
 1148

Liquid-phase process	Case name	Formulations
-	Control run	$A_u = 1350 \times q_c^{2.47} (N_c \times 10^{-6})^{-1.79} \rho_a^{-1.47}$ $A_c = 67 \times (q_c q_r)^{1.15} \rho_a^{-2.3}$
Autoconversion	Be68	$A_u = \frac{3.5 \times 10^{-2} q_c^2}{0.12 + 1.0 \times 10^{-12} \frac{N_c}{q_c}}$
	Bh94	$A_u = 6.0 \times 10^{28} n^{-1.7} (q_c \times 10^{-3})^{4.7} (N_c \times 10^{-6})^{-3.3}$
	LD04	$A_u = 1.1 \times 10^{13} \left[\frac{(1 + 3\varepsilon^2)(1 + 4\varepsilon^2)(1 + 5\varepsilon^2) q_c^3}{(1 + \varepsilon^2)(1 + 2\varepsilon^2)} \frac{1}{N_c} \right]$ $\times \frac{1}{2} (x_c^2 + 2x_c + 2)(1 + x_c) e^{-2x_c}$
Accretion	Ko13	$A_c = 8.53 \times q_c^{1.05} q_r^{0.98} \rho_a^{-2.03}$
	CP2k	$A_c = \frac{\pi}{6} \rho_W \rho_a K_1 \frac{N_c N_r}{\lambda_c^3} \left(\frac{A1}{\lambda_c^3} + \frac{B1}{\lambda_r^3} \right), \text{ if } R_r \geq 50 \mu\text{m}, \text{ and}$ $A_c = \frac{\pi}{6} \rho_W \rho_a K_2 \frac{N_c N_r}{\lambda_c^3} \left(\frac{A2}{\lambda_c^6} + \frac{B2}{\lambda_r^6} \right), \text{ if } R_r < 50 \mu\text{m}.$
Entrainment-mixing	INHOMO	$N_c = N_{c0} \left(\frac{q_c}{q_{c0}} \right)^\alpha, \quad \alpha = 1.$

1149

1150

1151 Table 2. Contingency table used to calculate the Heidke skill score (HSS). The elements
 1152 $a-d$ represent the numbers of “hits”, “false alarms”, “misses” and “correct negatives”,
 1153 respectively. p_t is the threshold value of precipitation in observation and simulations, p_s
 1154 is the value from simulations and p_o is the value from observations.

1155

	Observation $p_o > p_t$	Observation $p_o \leq p_t$
Simulation $p_s > p_t$	a	b
Simulation $p_s \leq p_t$	c	d

1181 Figure 2. Spatial distributions of 48 h accumulated precipitation (mm) from 0000 UTC

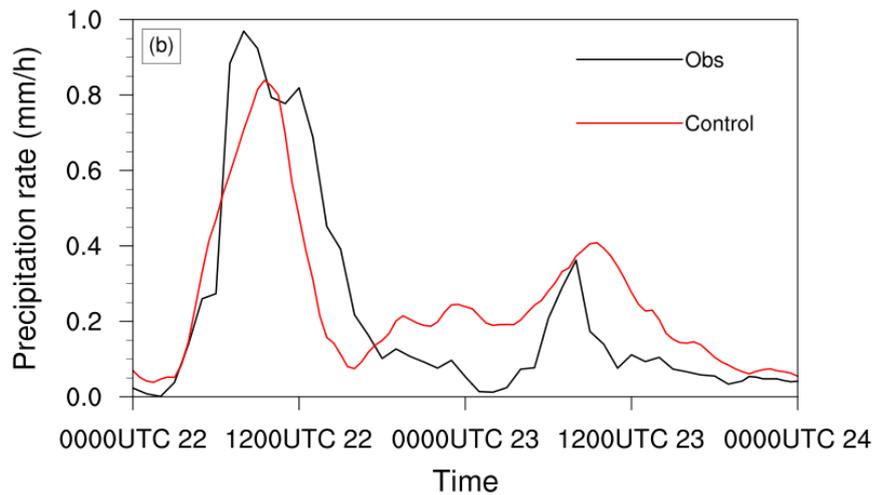

1182 22 July to 0000 UTC 24 July 2014 in the observations and the control run over domain

1183 02 (a, b) and domain 03 (c, d).

Area-averaged 1-h precipitation rate for domain 02

Area-averaged 1-h precipitation rate for domain 03

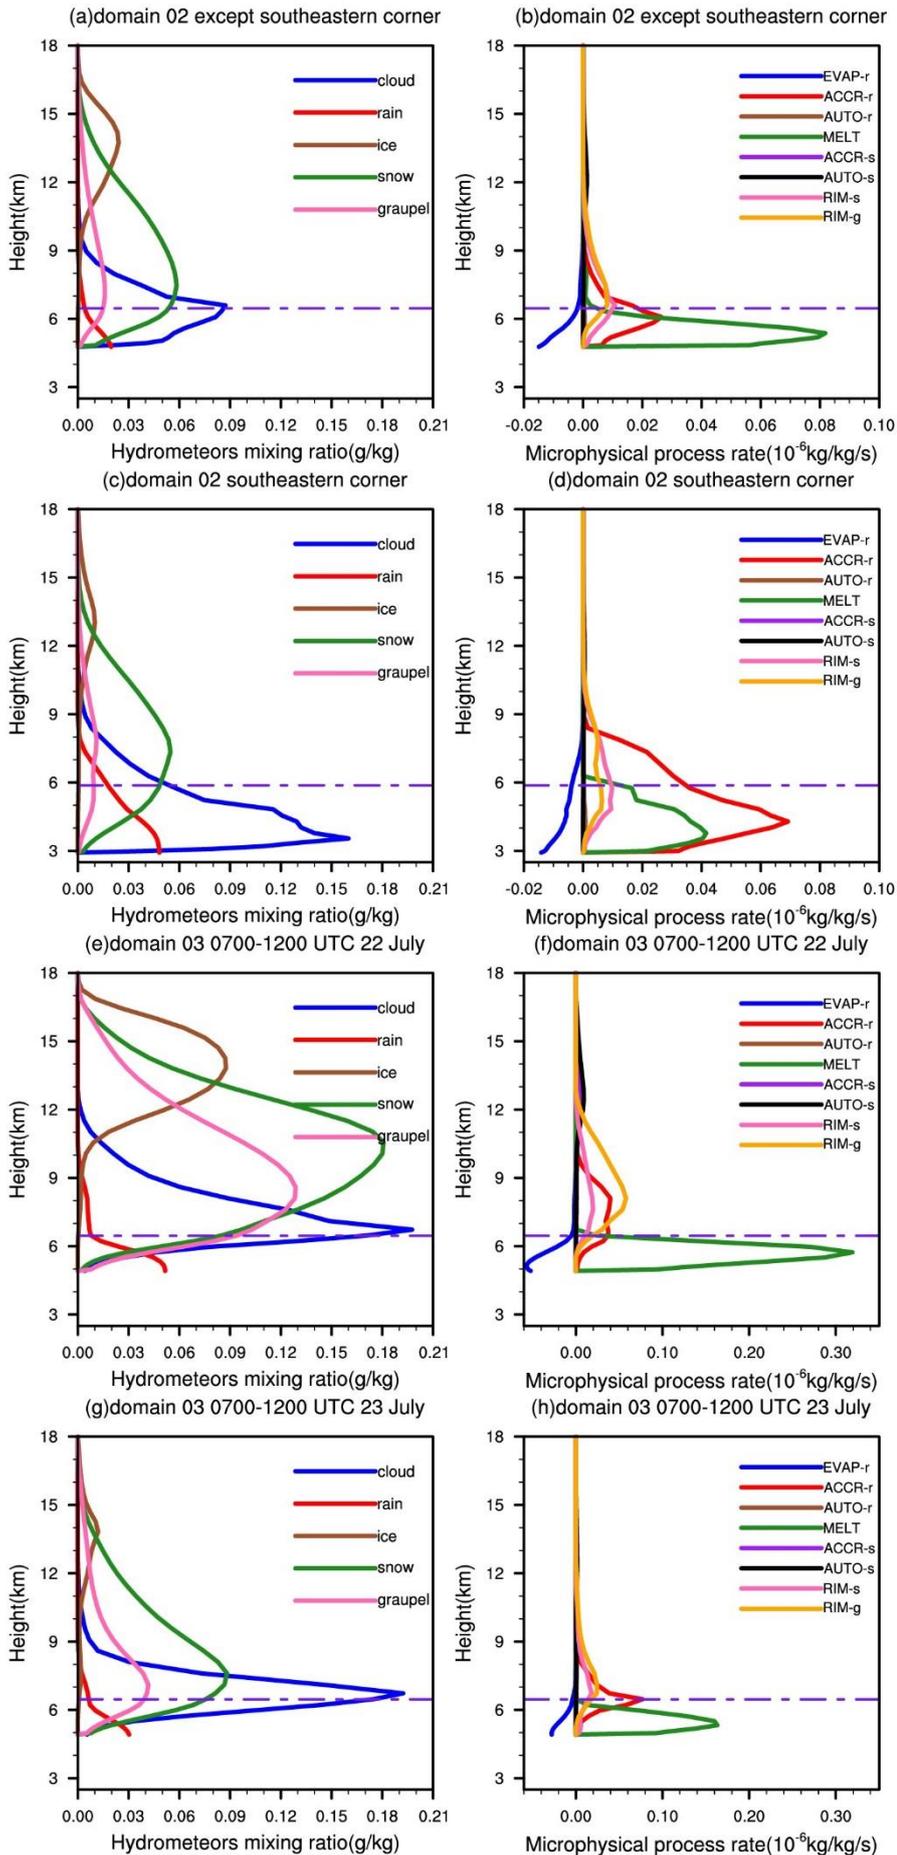

1184

1185 Figure 3. Time series of area-averaged hourly precipitation rate (mm/h) from 0000 UTC

1186 22 July to 0000 UTC 24 July 2014 over (a) domain 02 and (b) domain 03 in the

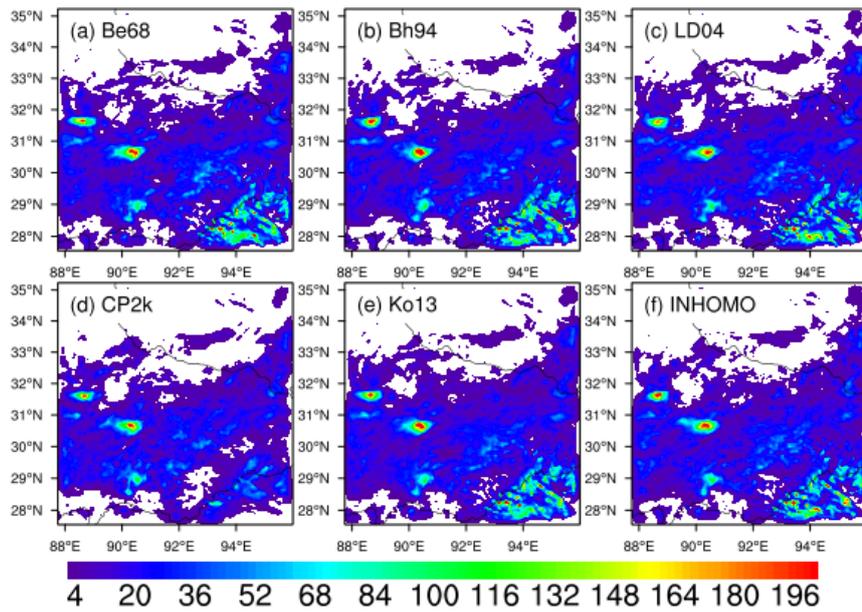

1187 observations and the control run.

1188

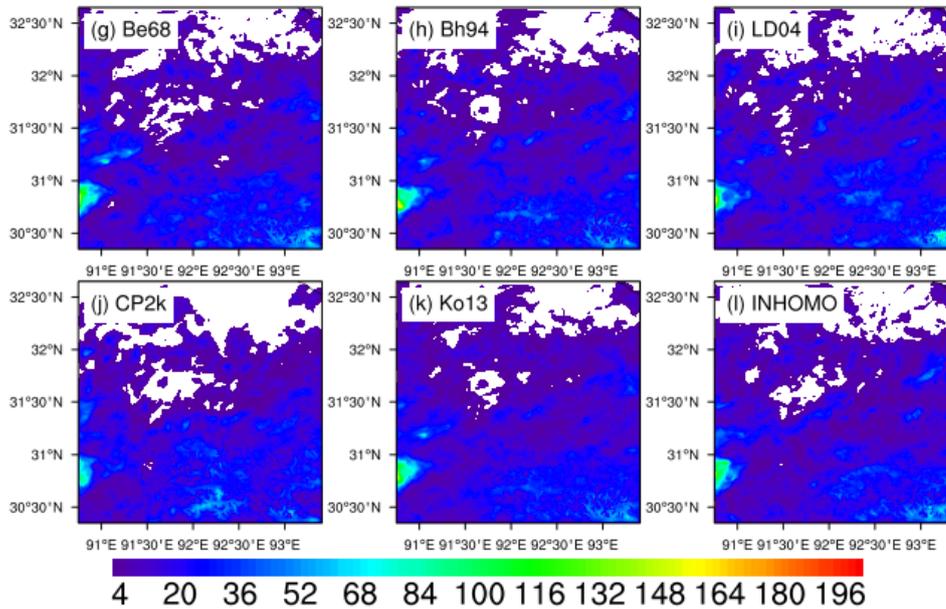

1190 Figure 4. Mean vertical profiles of mixing ratios (g/kg) of cloud droplets (q_c), raindrops
1191 (q_r), ice particles (q_i), snow particles (q_s), graupel particles (q_g) and their primary
1192 microphysical processes in the control run (a, b) averaged for 48 h over domain 02
1193 except southeastern corner, (c, d) averaged for 48 h at the southeastern corner over
1194 domain 02, averaged during two precipitation peaks (e, f) 0700-1200 UTC 22 July 2014
1195 and (g, h) 0700-1200 UTC 23 July 2014 over domain 03. The purple dot-dash lines
1196 denote the heights of 0 °C isotherm. The meanings of the symbols in the legends are
1197 shown in Appendix A.

48h accumulated precipitation for domain 03(mm)

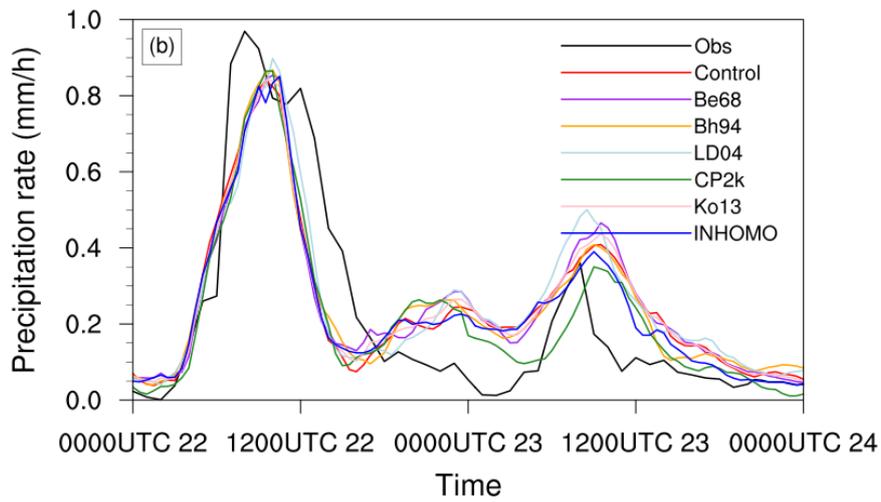

1199

1200 Figure 5. Spatial distributions of 48 h accumulated precipitation (mm) during 0000
 1201 UTC 22 July to 0000 UTC 24 July 2014 from observations and all sensitivity
 1202 simulations over (a-f) domain 02 and domain 03.

Area-averaged 1-h precipitation rate for domain 02

Area-averaged 1-h precipitation rate for domain 03

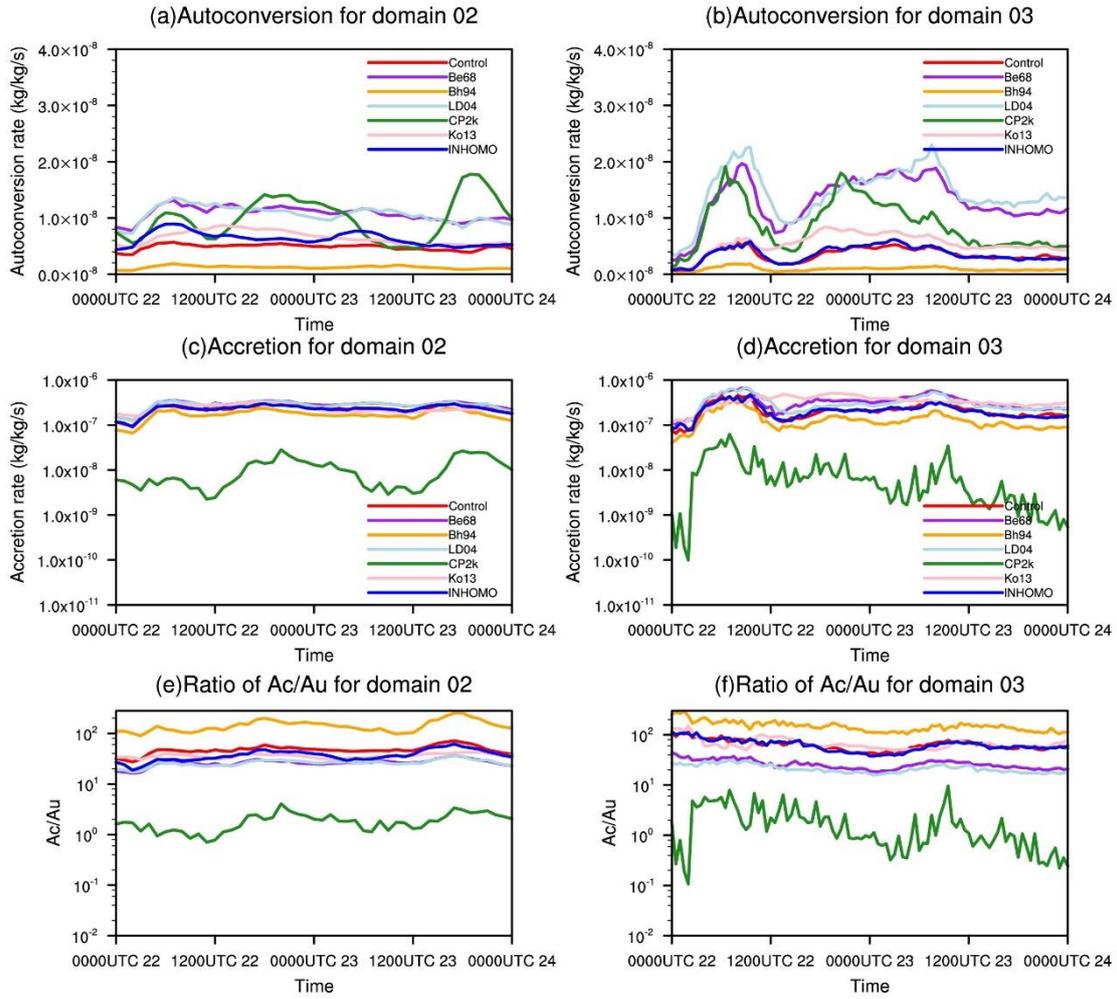

1203

1204 Figure 6. Time series of area-averaged hourly precipitation rate (mm/h) from 0000 UTC

1205 22 July to 0000 UTC 24 July 2014 over (a) domain 02 and (b) domain 03 from the

1206 observations and all simulations.

1207

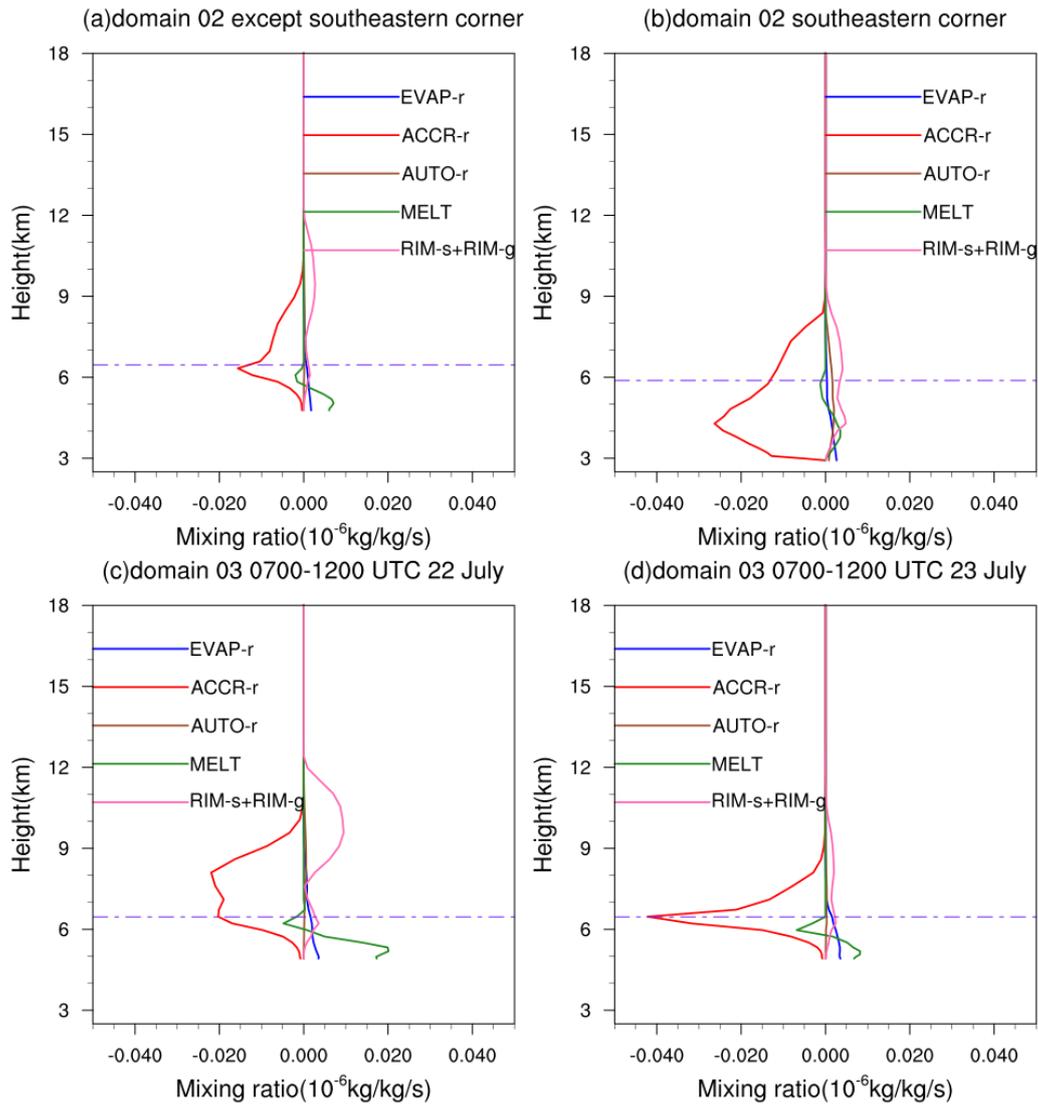

1208

1209 Figure 7. The time series of area-averaged autoconversion rate, accretion rate, and the

1210 ratio of accretion rate to autoconversion rate (A_c/A_u) over (a, c, e) domain 02 and (b, d,

1211 f) domain 03 for all simulations, respectively.

1212

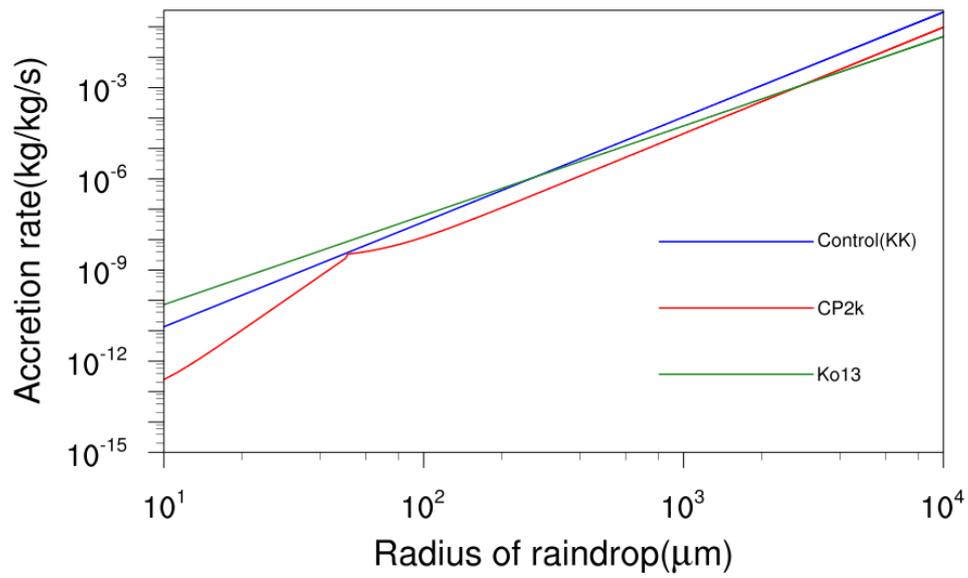

1213

1214 Figure 8. Differences of mean vertical profiles of the dominated microphysical
 1215 processes conversion rates between CP2k and the control run (CP2k-Control) from (a)
 1216 domain 02 except the southeastern corner, (b) the southeastern corner of domain 02,
 1217 and during the two precipitation peak periods (c) 0700-1200 UTC 22 July and (d) 0700-
 1218 1200 UTC 23 July over domain 03. The purple dot-dash lines denote the heights of 0 °C
 1219 isotherm. The meanings of the symbols in the legends are shown in Appendix A.

1220

1221

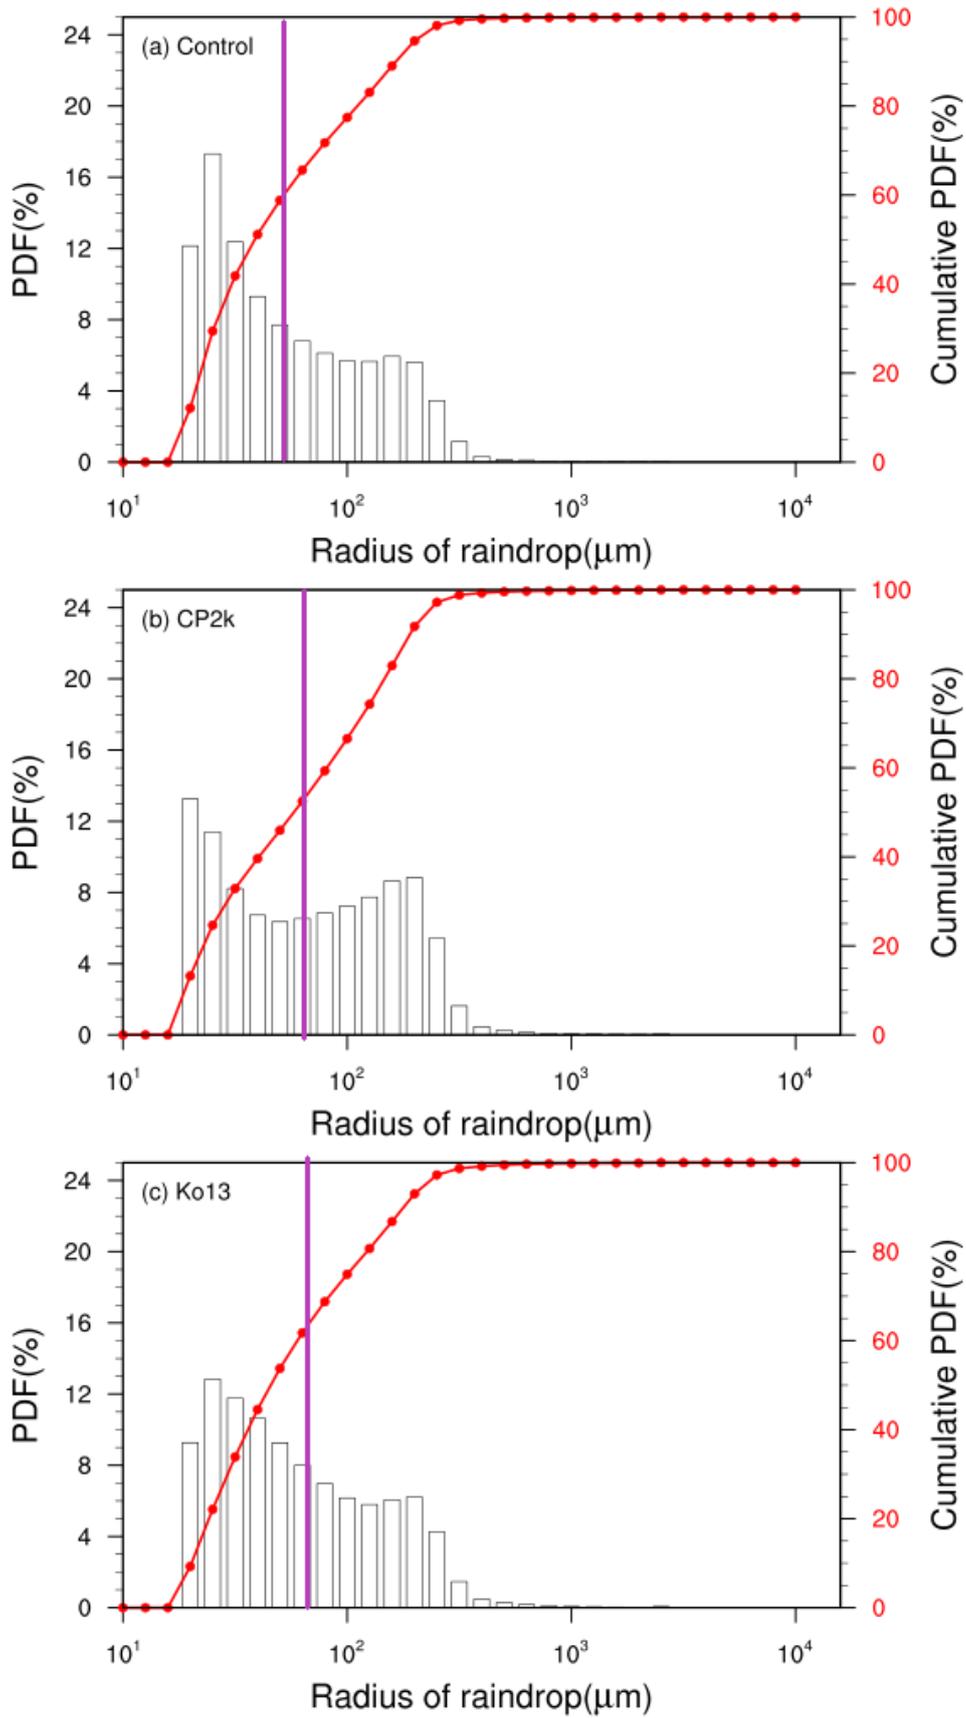

1222

1223 Figure 9. The accretion rate as a function of raindrop radius with fixed cloud mixing

1224 ratio $q_c = 1 \text{ g/kg}$, the radius of cloud droplet $R_c = 10 \text{ μm}$, number concentration of

1225 raindrops $N_r = 4000 \text{ /m}^3$ for the three accretion schemes.

1226

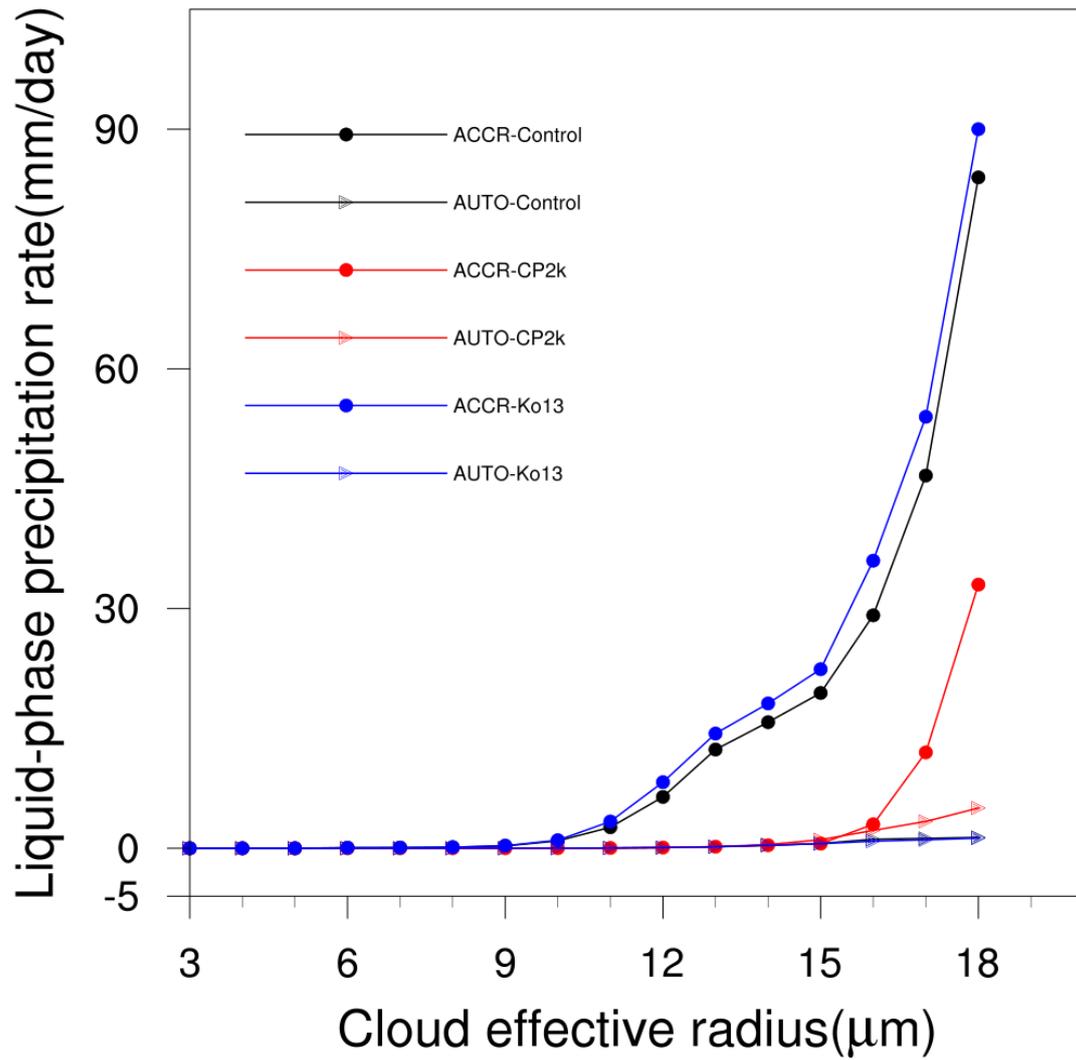

1227

1228 Figure 10. Probability distribution function (PDF) and cumulative PDF of raindrop

1229 radius involved in the accretion process for (a) the control run, (b) CP2k, and (c) Ko13.

1230 The purple line denotes the radius of raindrop equal to 50 μm .

1231

1232

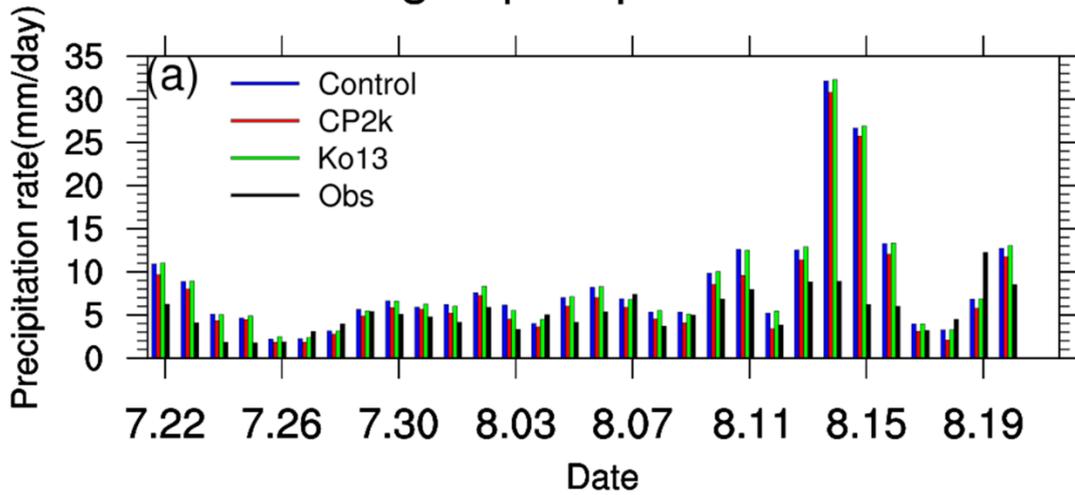

1233 Figure 11. Dependence of liquid-phase precipitation intensity on cloud effective radius

1234 from the three accretion schemes during 0000 UTC 22 July to 0000 UTC 24 July 2014

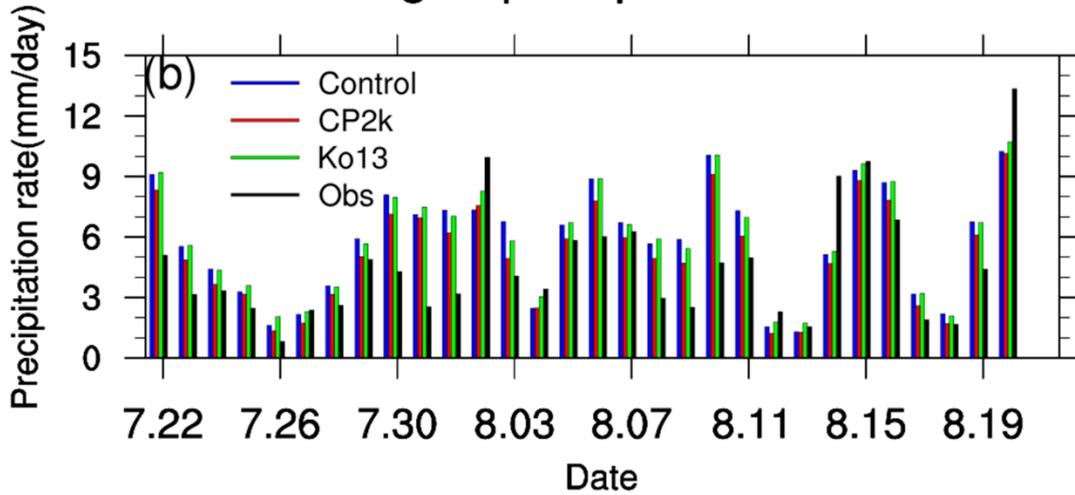

1235 over domain 03.

1236

Area-averaged precipitation rate for d02

Area-averaged precipitation rate for d03

1237

1238 Figure 12. Time series of area-averaged daily precipitation rate (mm/day) from 0000

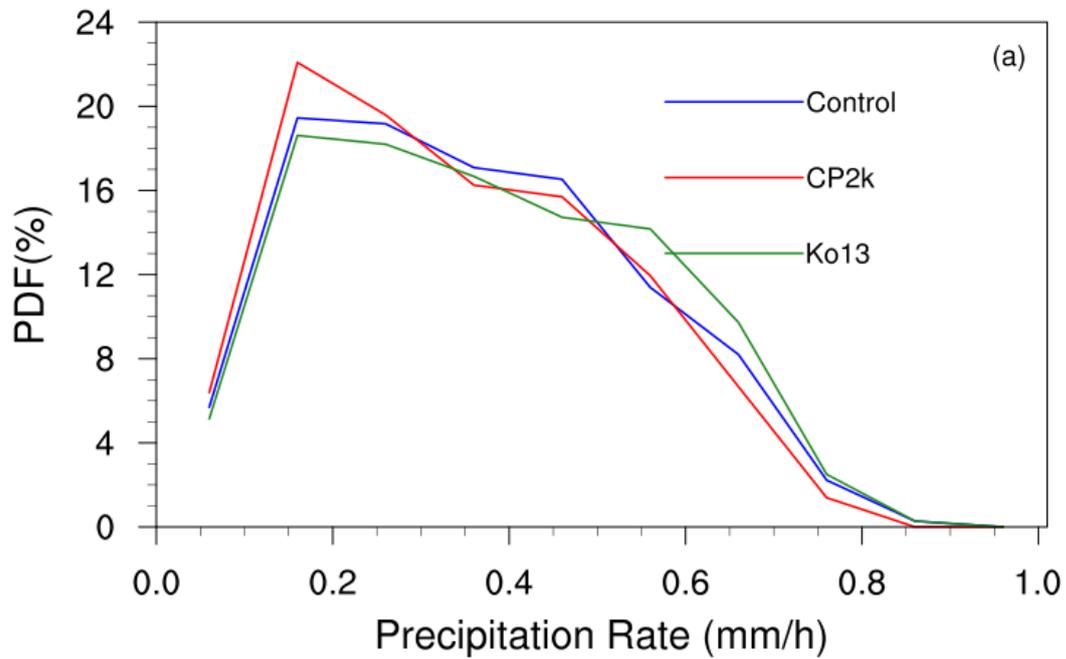

1239 UTC 22 July to 0000 UTC 20 August 2014 over (a) domain 02 and (b) domain 03 in

1240 the observations and three accretion cases (the control run, CP2k and Ko13).

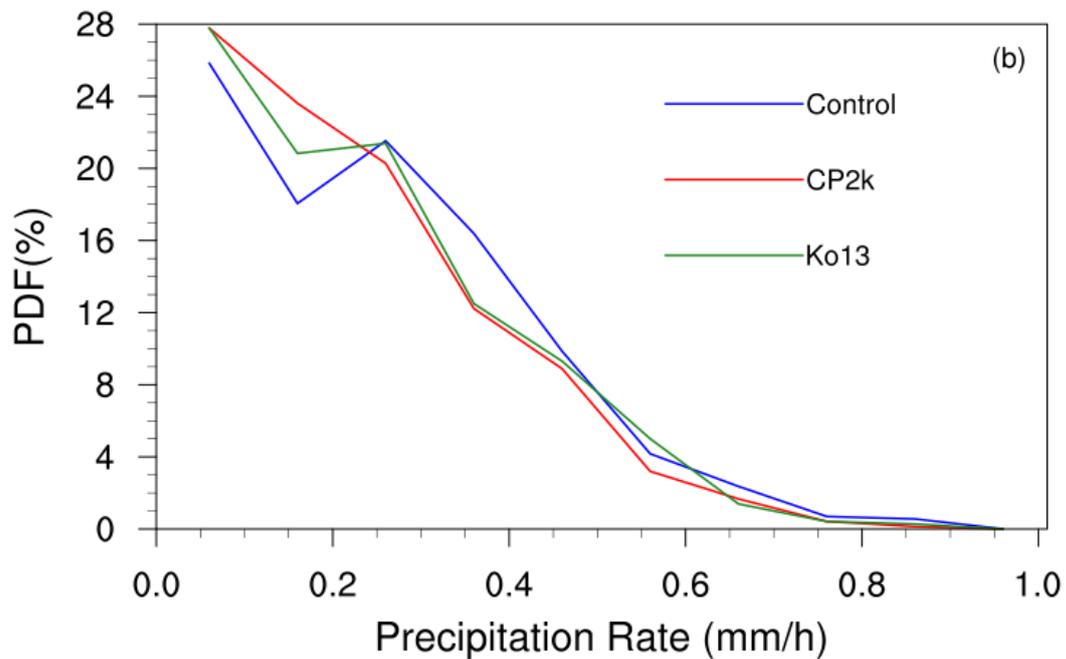

1241

1242

PDF of precipitation rate for domain 02

PDF of precipitation rate for domain 03

1243

1244 Figure 13. Probability distribution function (PDF) of precipitation rate (mm/h) from
1245 0000 UTC 21 July to 0000 UTC 21 August 2014 over (a) domain 02 and (b) domain 03
1246 in the three accretion cases (the control run, CP2k and Ko13).
