RADIOLOGICAL AIR MONITORING AT THE BNL SITE

DQO START DATE January 1, 2003

REVISION NUMBER/DATE Rev. 3, October 27, 2017

IMPLEMENTATION DATE January 1, 2018

POINT OF CONTACT Tim Welty (631) 344-4212

SUMMARY OF PROPOSED CHANGES

There are no proposed changes for calendar year (CY) 2018.

DESCRIPTION AND TECHNICAL BASIS

Airborne emissions can be generated from various facilities at BNL during operations, research, and scientific activities. The Laboratory’s environmental protection program implements engineering, as well as administrative, controls to prevent, reduce, and/or eliminate air pollutants from emission to the environment. Pollution prevention/control technologies, such as high efficiency particulate air (HEPA) filters or charcoal filters, are applied when potentially toxic pollutants are expected. BNL conducts both air surveillance and facility emissions monitoring to assess the adequacy of these controls to protect human health and determine any impact of air pollutants on the environment.

Environmental surveillance involves the analysis of particulate matter collected on filters, as well as water vapors chemically trapped in a collection medium. Specific diffuse sources, where particulates/gases could become airborne due to environmental restoration activities, are also monitored, as needed. Dose impacts that have the potential to exceed National Emissions Standards for Hazardous Air Pollutants (NESHAPs) limits are calculated to show compliance with DOE requirements, federal and state laws and regulations, and industry standards.

DRIVERS FOR AIR MONITORING AT THE BNL SITE

- Compliance
- Support compliance
- Surveillance
- Restoration

- Environmental Protection Agency (EPA) regulation 40 CFR 61, Subpart H requires DOE facilities to monitor for radiological discharges and to estimate the radiological dose to the public.

DOE Order 458.1 establishes a primary radiation protection standard for members of the public at 100 mrem/yr effective dose equivalent (EDE) for prolonged exposure from all sources, including air emissions. For air, derived concentration guides (DCGs) listed in DOE Standard 1196 specify the concentrations of radionuclides that can be inhaled without exceeding the DOE primary radiation protection standard for the public. The order also states that facilities should have the capability, consistent with the types of operations conducted, to monitor routine and unplanned releases and to assess dose impact to members of the public.

BNL’s air monitoring is governed by the Clean Air Act (CAA). The fundamental objective of the CAA is to protect human health and the environment from air pollutants. The CAA enables EPA to define and establish standards and criteria for air pollutants that are of major concern. These pollutants and the National Primary and Secondary Ambient Air Quality Standards (NAAQS) are defined in 40 CFR 50. In 1990, Section 112 of the CAA, NESHAPs 40 CFR 61, was amended by Title III. Title III lists 189 hazardous air pollutants (HAPs), of which radionuclides are counted as one, and calls for emission reductions of air toxics and imposes new standards on both new and existing sources. While standards have not yet been set for many hazardous air pollutants, a dose limit has been established for radionuclides.

**DATA QUALITY OBJECTIVE ANALYSIS**

**Step 1: State the Problem**

BNL’s research operations and scientific activities could potentially impact human health and the environment. Therefore, the emissions surveillance program to qualitatively quantify the radiological emissions is a regulatory requirement. DOE/EH-0173T states that all DOE operations shall properly and accurately measure radionuclides in their effluents and in the ambient environmental media with provisions for the detection and quantification of unplanned releases of radionuclides to the environment. This guidance document also specifies that the surveillance program shall characterize the radiological conditions at off-site environment locations, estimate public doses, confirm predictions of public dose based on effluent monitoring data and modeling, and provide compliance data for all applicable environmental regulations. The guidance document further states that surveillance may be necessary for legal reasons, public concerns, and/or state and local commitments.

There is motivation to reduce the costs of environmental monitoring due to budget constraints. The historical tritium air surveillance data collected at the Laboratory has shown that tritium concentrations have been well below the minimum detection level (MDL) at most sampling locations following the shutdown of the reactors. Therefore, by streamlining the sampling program while retaining the capability to detect unplanned releases, the Laboratory has eliminated the redundant tritium sampling locations. Sampling for airborne tritium at the blockhouses is believed to be sufficient to monitor the few sources left on site. While air surveillance is necessary and is required to show compliance with the different regulations, monitoring of sources and collection of samples at four permanent monitoring stations is believed to be sufficient to document compliance with EPA and DOE requirements. A reduction in sample collection must support budget constraints on the environmental protection program. In addition, because less-detailed analysis of samples, such as gross alpha/gross beta analysis rather than gamma composite analysis, might
provide sufficient protection, gross alpha/gross beta sampling is implemented to achieve savings in monitoring costs as well.

Finally, blind duplicate quality assurance sampling is conducted to test the precision of sampling and analyses. At present, the duplicate station is permanently stationed at P7, which does not allow testing the sampling precision at other environmental sampling stations, although P7 is located downwind of the most significant emission points and in the predominant wind direction. The rotation of the duplicate sampling station would enhance the capability to compare and test the precision and accuracy of all the sampling locations rather than only the P7 location, as is currently done.

**Step 2. Identify the Decisions**

The desired decisions for the air surveillance and monitoring program are:

- Will the number of air samples collected and their frequency of collection be adequate to detect any potential impact from research operations?
- Will the regulatory compliance requirements for ambient air quality be met if air monitoring is reduced?
- Will the capability to confirm the effectiveness of current emission control systems continue to be adequate using reduced monitoring?
- Will the risk and dose to the members of the public exceed any threshold values, and will the data collected continue to be defensible?

**Step 3: Identify Inputs to the Decisions**

Environmental air surveillance samples shall be collected in accordance with Environmental Monitoring Standard Operating Procedures (EM-SOPs):

- BNL EM-SOP-500, Air Sampling at Permanent Monitoring Stations
- BNL EM-SOP-501, Tritium Air Sampling at Portable Stations

The particulate matter sampling media consists of a 5-cm (diameter) glass fiber air filter with a backing to hold the filter in place. Samples are collected weekly and counted for gross alpha and gross beta radiation using an anticoincidence proportional counter. Environmental air sample criteria are based on the premise that representative samples of the ambient air are taken continuously. The preferred sampling height is 1.5 meters above the ground and away from traffic, large buildings, or similar obstructions. Analyses for gamma-emitting nuclides that were performed on monthly composites were eliminated, since review of historical data has shown no detection of such radionuclides attributed to BNL operations.

The air is sampled bi-weekly for tritiated water vapor by drawing streams of air through silica gel cartridges. After collection, any entrapped liquid is extracted from the desiccant and analyzed for tritium using liquid scintillation techniques. In all cases, flow rates, media volumes, and exposure periods are such that the media are not likely to be saturated during the sampling period; high collection efficiencies are achieved in accordance with the manufacturer’s recommendations.

Specific inputs include:

- The highest concentrations expected above the MDL of the pertinent radionuclide in the vicinity of operations and their dispersion due to meteorological conditions.
Representative radionuclide concentrations in areas where public health is a concern, occupancy factors, and doses to the public through the air pathway from operations must remain as low as reasonably achievable, relative to standards.

- The existence of areas known to have potential for contamination; an increase in contamination via resuspension of particulates in those areas would require air monitoring.
- Frequency of review of actual emissions from facilities and in areas with surface and soil contamination.
- Pre-operational baseline data and any environmental surveillance data for areas near waste units that are scheduled for treatment or restoration to assess the integrated effects of individual site influence over time.
- Measurements at the site perimeter and in nearby communities.
- Continuous operation of the remaining on-site air monitors
- Use of thermoluminescent dosimeters (TLDs) to assess the environmental doses from unusual releases, if any.
- Review of analytical results by project managers in accordance with Environmental Protection Division (EPD) data review procedures.
- Trends of background concentration with historically collected data in each wind sector to assess the impact of site operations, if any.

**Step 4: Define the Study Boundaries**

Since 1972, the perimeter blockhouse ambient air monitoring stations have collected weapons test fallout data and natural background data. These stations are located in all the predominant wind directions and where warranted by site-specific meteorological conditions. Four of the six air particulate sample collection stations are situated within dedicated blockhouses. These sample collection stations, P2, P4, P7, and P9, are located at the boundary perimeter. At each station, glass fiber filter paper is used to capture airborne particulate matter and silica gel cartridges collect water vapor samples for Tritium detection and analysis. The population surrounding the Laboratory is beyond the sampling stations, which allows for the opportunity to detect and mitigate any unplanned releases.

**Step 5: Develop the Decision Rules**

If the tritium concentrations are greater than twice the 12-month trailing average, then request re-analysis of the sample, investigate the source of elevated tritium at that location, and implement corrective actions. The project manager will review all detections above the limits for comparison with historical values and significance. If the gross alpha activity in the filters is greater than twice the minimum detection limit (MDC), then request re-analysis of the sample and collect more samples in the vicinity. The project manager will review all detections above the limits for comparison with historical values and significance. If the gross beta activity in the filters is greater than twice the 12-month trailing average, then request a re-analysis of the sample and collect more samples in the vicinity. The project manager will review all detections above the limits for comparison with historical values and significance. All values greater than the above-stated gross alpha/beta concentration shall trigger an investigation of potential sources in that wind sector.

**Step 6: Specify Acceptable Limits on Decision Areas**

Air surveillance data are analyzed with the intent of satisfying the following goals:

- Estimate concentrations at each sampling point.
- Compare current concentrations to previous concentrations in order to identify changes or inconsistencies.
- Compare concentrations to established DCGs or permit limits.
- Compare concentrations at a single location, or a group of locations, to control or background locations and evaluate the reliability of the comparisons.

**Step 7: Optimize the Design**

The duplicate station at P7 shall be moved from one blockhouse to another and kept at each blockhouse for a period of two months to test the precision of all the environmental sampling and analyses. Facility process data is reviewed, and the effectiveness of emission controls in the relevant facilities and other remediation projects for potential source of emissions, if any, is assessed.

The air monitoring program shall be optimized based on the surveillance data, audits, and air surveillance assessments during the calendar year.

See Appendix B for the monitoring program for this DQO.
