REVIEWED BY: Barbara Youngberg DATE 8/17/00

### SUMMARY

On June 22, 2000, in order to confirm that radionuclide soil concentrations met established cleanup goals, two areas of AOC 16 (AOC 16E.2 and 16E.3) which had undergone remediation and one area consisting of soils determined to be below cleanup goals by the Segmented Gate System (SGS) were surveyed using a portable gamma radiation detection instrument, and 11 soil samples were obtained for laboratory analysis. Outside of (but nearby) AOC 16E.2, two areas were discovered that exhibited elevated radioactivity at 6x and 10x background. These zones were not identified by BNL as requiring remediation prior to this survey, even though the largest area was 4.5 feet in diameter (based on readings greater than 3x background). Three of the samples obtained exceeded cleanup goals for cesium-137, which indicates that AOC 16E.2 was not sufficiently remediated as of the date of this survey.

## INTRODUCTION

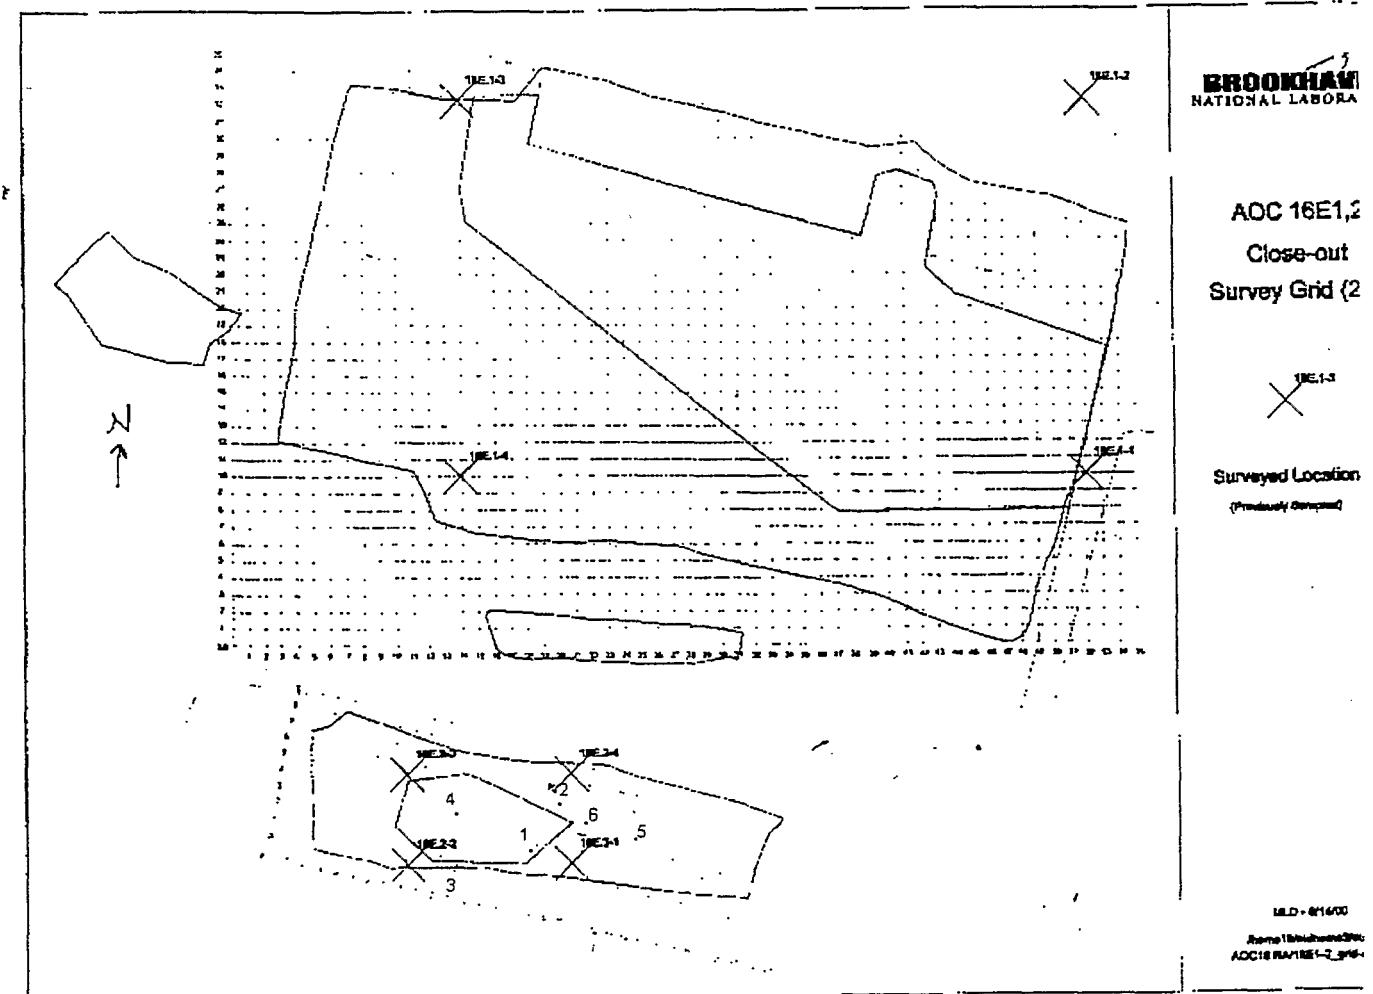

Aerial radiation surveys of BNL performed in 1980 and 1983 identified several unexpected areas on site that exhibited elevated radioactivity. Investigation of these areas identified the source as cesium-137 contaminated soils. These soils are believed to have come from the former Hazardous Waste Management Facility (HWMF), which was used for landscaping purposes throughout the site. Thus, these areas are known as the "Landscape Soils." The areas investigated during this survey were all south of Building 490, the Brookhaven Medical Research Reactor (BMRR).

As part of the AOC16 Final Status Survey, a member of the DEC's Radiation Section obtained confirmatory samples for radionuclide analysis after these areas were remediated. Some samples obtained were splits of samples obtained by this project's independent verification contractor (IVC), the Oak Ridge Institute for Science and Education (ORISE), others were independent based on DEC walkover survey results.

## MATERIALS AND METHODS

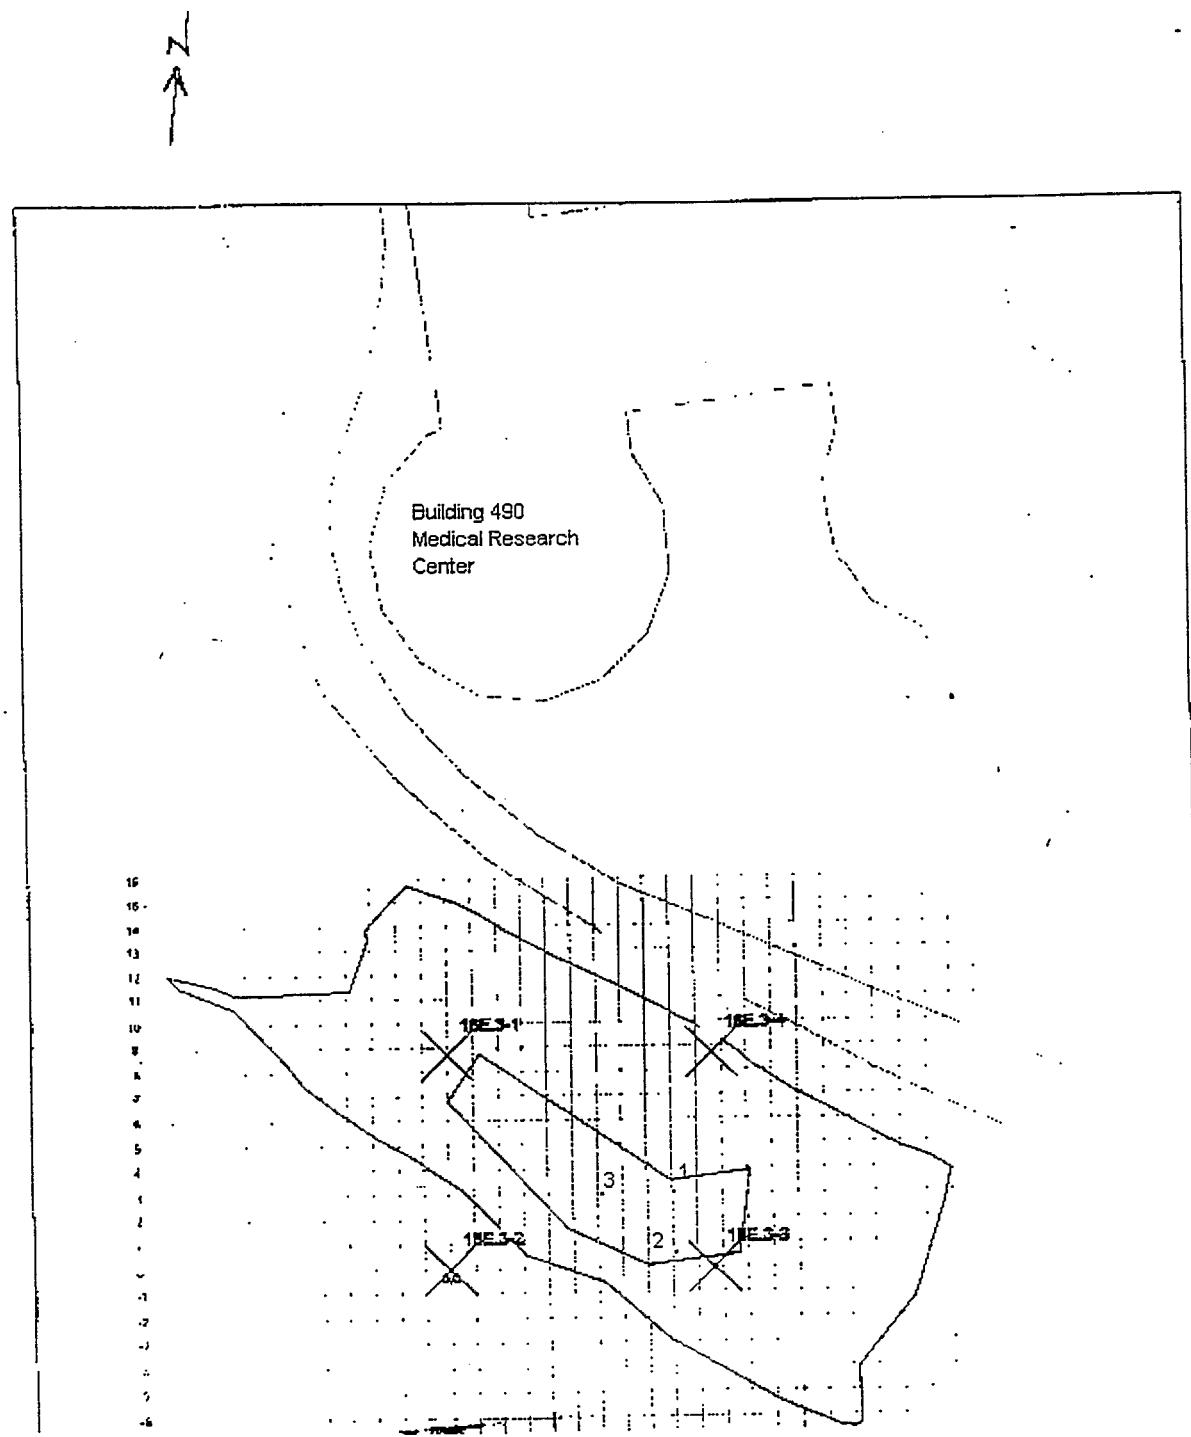

In total, eleven soil samples were taken from within and around the AOC 16E.2 and 16E.3 excavation areas. These were obtained from surface soils of the top 3 inches in all cases, removing any vegetation or large stones. Below are two diagrams showing the approximate sample locations.

Figure 1: Sample Locations in AOC 16E.2

Areas exhibiting elevated radioactivity that were detected outside of AOC 16E.2 are located at approximately sample locations 5 and 6 in Figure 1. The 60,000 CPM survey reading at the surface at the location of AOC 16E.2 sample 6 (NR100 0604S 062209) was small and localized (a few inches across), but the 96,000 CPM reading at AOC 16E.2 sample 5 (NR100 0604S 062208) was the maximum reading found in an area 4.5 feet in diameter (based on survey meter readings of greater than thrice background).

**Figure 2: Sample Locations in AOC 16E.3**

A gamma radiation detecting survey instrument was used to survey the excavated areas (Class 1 impacted areas in MARSSIM terminology) and the surrounding areas (Class 2 impacted) on June 22. Details of the instrument are provided below.

Background was 6500 counts per minute (CPM) in the areas surrounding AOC 16E.2 and 9500 CPM in the areas surrounding AOC 16E.3. This instrument was satisfactorily checked in Albany prior to leaving for BNL on June 19, 2000, and again upon return on June 23, 2000. In addition, checks using a field check source (as opposed to the one used in our offices) was developed on June 21, and the meter checked out properly on June 22, the day of use. No abnormalities were noted in instrument performance.

SURVEY INSTRUMENT: Meter: Ludlum Model 2221 Portable SCA, S/N 132864

Calibrated On: August 2, 1999

Probe:Ludlum Model 44-10 Scintillation Detector,  
S/N PR135862  
2"×2" NaI(Tl) scintillator

## RESULTS

The summary below reports the highest results reported from either of the duplicates for sample 062201, which was the only sample duplicate analyses were performed on. Included in the Appendix to this report is the original laboratory analysis results for these samples. Survey meter readings are provided for each sample location, and are discussed in the "conclusions" section of this report.

#### Notes on Sample Results

If the analysis result was less than the minimum detectable activity for the analysis, the nuclide is listed as "Not Detected." In the case of duplicate samples, "Not Detected" means that neither sample showed detectable activity for the nuclide in question.

Note 1 - The reported error is at least 50% of the reported activity.

Note 2 - The reported activity is at the detection limit (MDA) of the analytical procedure.

Note D - This nuclide was not detected in the duplicate sample.

#### INTERPRETATION OF RESULTS

Three of the samples analyzed exceeded the 23 pCi/g primary remediation goal for cesium-137. Determination of whether a site meets remediation goals is more than a matter of ensuring that the primary radionuclide contaminant is below guidelines. It further entails checking that (a) each radionuclide contributing to the dose be below its respective guideline and (b) that the resultant total contribution from all involved nuclides does not exceed the applicable dose limit. Radionuclide concentrations are compared to the cleanup goals developed for radiologically contaminated soils on-site, based on a 15 mrem/year dose limit, specified in the *Record of Decision, Operable Unit I and Radiologically Contaminated Soils* (OU I ROD), dated August 25, 1999. The goals specified in the OU I ROD are 23 pCi/g of cesium-137, 15 pCi/g of strontium-90, and 5 pCi/g of radium-226. For other radionuclides, the concentration goals are those developed for these Landscaping Soils.

In order to determine which of the samples obtained exceed the 15 mrem/year dose limit, a "sum of ratios" was calculated which divides each detected radionuclide concentration by its cleanup goal and then summing all these ratios together. A sum less than one indicates that the combined effect of a large area contaminated with that radionuclide concentration would result in a dose less than 15 mrem/year, a sum equal to one means the dose from a large area with that concentration would equal 15 mrem/year, and a sum greater than one would result in a dose exceeding 15 mrem/year.

and thus exceeds the remediation goal. Sums of ratios (SOR) were calculated using the following equation (in which [Cs-137] means "concentration of cesium-137 in pCi/g"):

$$SOR = \frac{[Cs-137]}{23} + \frac{[Sr-90]}{15} + \frac{[Ra-226]}{5} + \frac{[Co-60]}{1160} + \frac{[Am-241]}{40} + \frac{[Pu-238]}{66} + \frac{[Pu-239/240]}{40}$$

Uranium isotopes were ignored in this comparison since none of their concentrations exceeded expected background values for uranium in soil, and it is not desired to remediate areas due to normally present natural isotopes. The sums of ratios for each sample are provided in Table 1, below. Radium-226 results, even though a natural radionuclide whose concentration was detected at expected background levels, is included in Table 1 because a cleanup goal for it is specified in the OU I ROD. However, all of the exceedences of unity for the SOR were due only to high concentrations of cesium-137 in soil.

Table 1: Calculated Sums of Ratios

Sample Number	Identified Isotopes	Sum of Ratios (SOR)
062201	Cs-137, Ra-226, Am-241, Pu-239/240	0.794
062202	Cs-137, Ra-226, Am-241	0.568
062203	Cs-137, Ra-226	0.166
062204	Cs-137, Ra-226	0.896
062205	Cs-137, Ra-226, Am-241	0.891
062206	Cs-137, Ra-226, Am-241, Pu-239/240	<b>2.46</b>
062207	Cs-137, Ra-226	0.095
062208	Cs-137, Co-60, Pu-239/240	<b>9.24</b>
062209	Cs-137, Ra-226, Pu-239/240	<b>2.58</b>
062210	Cs-137, Ra-226, Am-241	0.597
062211	Cs-137, Ra-226	0.384

Cesium-137 was detected in all eleven samples obtained, at concentrations ranging from 0.6 to 205 pCi/g. Three samples, 062206, 062208, and 062209, exceeded the cleanup goal set at 23 pCi/g for this isotope. Americium-241 was detected at low concentrations in five samples, but in each case the large relative error of the results (and in one case the additional lack of a confirmed detection in the duplicate analysis) indicates that these detections are false positive results. Cobalt-60 was detected at 0.7 pCi/g in only one sample, 062208. Plutonium-239/240 was detected in four samples, but in three cases the large relative error of the analysis and low concentrations detected (less than 0.3 pCi/g) indicates that these detections are false positive results as well. Only one Pu-239/240 detection, also for sample 062208, significantly exceeded its minimum detection limit and had low enough relative error to indicate an actual detection. The detection of nearly 13 pCi/g of Pu-239/240 in this sample indicates its source is not atmospheric deposition of fallout from weapons tests.

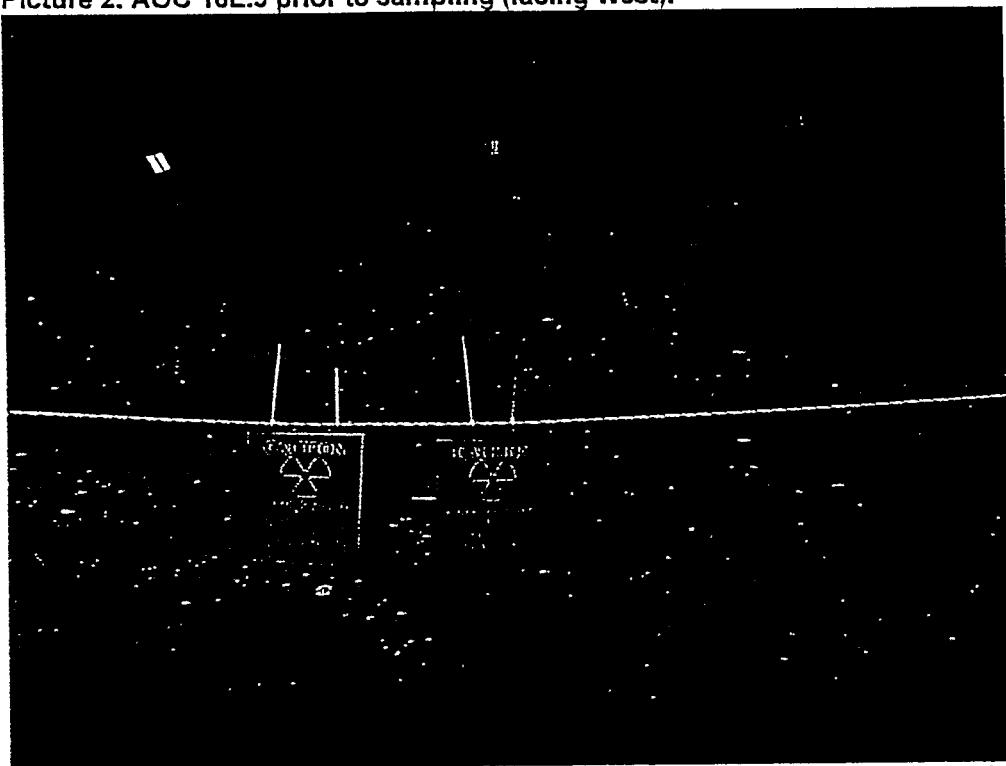

Sample 062208 was taken from the rather large area exhibiting elevated radioactivity to the east of AOC 16E.2 (shown in picture 1, below). In addition to the high concentration of cesium-137 detected, two other aspects of this sample indicate that the source of this material may be something different than the other landscape soils. Sample 062208 was the only detection of cobalt-60 of any of these samples and it also exhibited a high concentration of plutonium-239/240. Although the source of this material is likely the former HWMF (from an area with more cobalt and plutonium contamination than other areas), it is also possible that the source of this contamination is some other event entirely. Although 062208 was taken from the area exhibiting the maximum survey meter reading, the contamination (exceeding 30,000 CPM on the survey meter) extended approximately 2.25 feet in all directions from the maximum reading in a rough circle.

**Picture 3: SGS processed soil piles (facing East)**

## CONCLUSION

No concentrations of radionuclides exceeding cleanup goals was detected in or around AOC 16E.3. However, two areas outside of the identified soil contamination area AOC 16E.2 and one area within it were discovered to contain concentrations exceeding cleanup goals. Additional remediation should be conducted in these areas prior to declaring AOC 16E.2's remediation is complete.

Questions must be raised concerning BNL's ability to properly conduct Class 2 Impacted Area surveys in accordance with MARSSIM (NUREG-1575) due to the extent and position of the two areas discovered outside of AOC 16E.2. Neither of these areas were at all difficult to distinguish from background levels and neither of them were found more than a few feet away from the identified soil contamination area.

Because the larger of the previously unidentified areas was along the roadway leading to the side of Building 494, a walkover survey was performed from the edge of the roadway to approximately 30 feet parallel to it. No additional areas of contamination were evident.

Date of Report

**ACCOMPANYING STAFF:** William Varcasio

**REVIEWED BY:** Barbara Youngberg      **DATE** 11/22/00

### SUMMARY

Confirmation surveys were performed of all regions of Sub-Areas of Concern (Sub-AOC) 16 selected for remediation as contaminated landscaping soils in BNL's *OU 1 and Radiologically Contaminated Soils Record of Decision* (ROD), except AOC 16E.3, which was completed during the survey conducted on June 22, 2000. Survey dates in this report are separated by one month due to additional contamination being removed after our initial survey was performed. Significant improvement in soil radionuclide concentrations and radiation readings were noted when comparing the October 11 radiation survey to September's survey.

## INTRODUCTION

Aerial radiation surveys of BNL performed in 1980 and 1983 identified several unexpected areas on site that exhibited elevated radioactivity. Investigation of these areas identified the source as cesium-137 contaminated soils. These soils are believed to have come from the former Hazardous Waste Management Facility (HWMF), which was used for landscaping purposes throughout the site. Thus, these areas are known as the "Landscape Soils."

As part of the AOC16 Final Status Survey, staff from DEC's Radiation Section obtained confirmatory samples for radionuclide analysis after these areas were remediated. Some samples obtained were splits of samples obtained by this project's independent verification contractor (IVC), the Oak Ridge Institute for Science and Education (ORISE), others were independent based on DEC walkover survey results. Because widespread residual radioactive contamination greater than cleanup goals was detected by ORISE and DEC staff during the September survey, and because BNL performed additional remediation after the September survey, additional surveying and sampling was performed by DEC staff on October 11, 2000.

In addition to areas described in the OU I ROD, BNL identified and investigated two new sub-AOCs, AOC 16E.4 and AOC 16S.6.f during their remediation of AOC 16. AOC 16E.4 is a small area close to the BMRR, and AOC 16S.6.f is an area near the Linear Accelerator.

## MATERIALS AND METHODS

The *Multi-Agency Radiation Survey and Site Investigation Manual* (MARSSIM, NUREG-1575) will be referenced repeatedly in this report.

Areas of AOC 16 known or suspected to contain radioactive contamination greater than cleanup goals (known in MARSSIM terminology as "Impacted Class 1" areas) had 100% walkover surveys performed using hand-held gamma radiation detection instruments. The following sub-AOCs had gamma walkover surveys performed: 16E.1, 16E.2, 16E.4, 16F, 16G, 16S.1-5, 16S.6.a-f. Additional walkover surveys covering about 30% of the total region were performed in areas surrounding these Class 1. These surrounding areas are classified in MARSSIM as "Impacted Class 2" areas.

Based on the results of these walkover surveys, initially 25 soil samples were taken from near and within excavated areas of the following sub-AOCs: 16E.1, 16F, 16G, 16S.5, 16S.6.a, 16S.6.e, 16S.6.f. These were typically obtained from the top three inches of surface soils remaining after remedial activities, after removing any vegetation or large stones. During the first survey, soil samples were collected on two days, September 6 and September 7. These dates are reflected in the last six digits of the sample numbers in Table 1, below. The date is specified first (0906 for September 6, for example) and then the numerical order of that day (01, 02, etc.).

Because of the elevated results of the September survey, additional surveying and sampling took place on October 11, 2000 to verify the completeness of BNL's continuing remediation of AOC16. Eight additional soil samples were obtained on this date, typically from the highest survey meter reading in the area. Areas with concentrations of cesium-137 exceeding the cleanup goal identified during the first survey were re-scanned and re-sampled to determine residual radionuclide levels.

Details of the two gamma radiation detecting survey instruments that were used to survey the excavated and surrounding areas are provided below. Background generally varied between 6000 and 8500 counts per minute (CPM) in the areas outside of the excavated zones. Instruments were satisfactorily checked in Albany prior to leaving for BNL, and again upon return to Albany. No abnormalities were noted in instrument performance. The instrument consistently used inside of the Class 1 areas has serial number 132864.

S/N PR135862      2"×2" NaI(Tl)

Included in Appendix 1 to this report are survey maps and sample locations for the surveyed areas of AOC 16. In the case of one area, AOC 16S.6.f, we were not provided a survey map by BNL, so a simple diagram is included. It does not include the same coordinate system defined for the other sub-AOCs, and no such coordinates are reported in Table 1, on the next page.

## RESULTS

Included in Appendix 2 to this report are the original laboratory analysis results for these samples and a summary sheet. The summary sheet provides radionuclide concentrations in picocuries per gram (pCi/g), calculation of the Sum of Ratios (SOR - see next section) and fixed survey meter readings for each sample. Background was not subtracted from these meter readings, in an attempt to provide unaltered "as-read" data, but typical background was in the 7000 - 8000 CPM range (some cases, of course, being slightly lower or higher).

An attempt in Appendix 2 is made to compare survey meter CPM reading to the cesium-137 activity in the sample in the form of a ratio, but this ratio varied greatly from 374 CPM/(pCi/g) to 43294 CPM/(pCi/g). It was noted that generally the higher the soil concentration is, the higher this ratio becomes. This wide variation demonstrates that

survey meter readings cannot reliably predict soil concentrations at this site, and physical samples must be analyzed to provide actual soil concentrations.

**Table 1: Sample locations**

Sample ID	Location (see maps in Appendix 1)	Coordinate
NR100 0902S 090601	AOC 16F-1, South of Manholes	(23E, 9N)

## INTERPRETATION OF RESULTS

Fourteen of the samples analyzed exceeded the 23 pCi/g primary remediation goal for cesium-137. Twelve of these samples were obtained during the first survey, which identified localized areas of soil contamination for further remediation. The last two samples (101101 at 36 pCi/g and 101107 at 25 pCi/g) were obtained from small areas exhibiting the maximum survey meter reading of the surrounding environs.

Determination of whether a site meets remediation goals is more than a matter of ensuring that the primary radionuclide contaminant is below guidelines. It further entails

checking that (a) each radionuclide contributing to the dose be below its respective guideline and (b) that the resultant total contribution from all involved nuclides does not exceed the applicable dose limit. Radionuclide concentrations are compared to the cleanup goals developed for radiologically contaminated soils on-site, based on a 15 mrem/year dose limit, specified in the *Record of Decision, Operable Unit I and Radiologically Contaminated Soils* (OU I ROD), dated August 25, 1999. The goals specified in the OU I ROD are 23 pCi/g of cesium-137, 15 pCi/g of strontium-90, and 5 pCi/g of radium-226. For other radionuclides, the concentration goals are those developed for these Landscaping Soils.

In order to determine which of the areas exceed this 15 mrem/year dose limit, a "sum of ratios" was calculated which divides each soil sample's detected radionuclide concentration by its cleanup goal and then summing all these ratios together. A sum less than one indicates that the combined effect of a large area contaminated with that radionuclide concentration would result in a dose less than 15 mrem/year, a sum equal to one means the dose from a large area with that concentration would equal 15 mrem/year, and a sum greater than one would result in a dose exceeding 15 mrem/year and thus exceeds the remediation goal. Sums of Ratios (SOR's) were calculated using the following equation (in which [Cs-137] means "concentration of cesium-137 in pCi/g"):

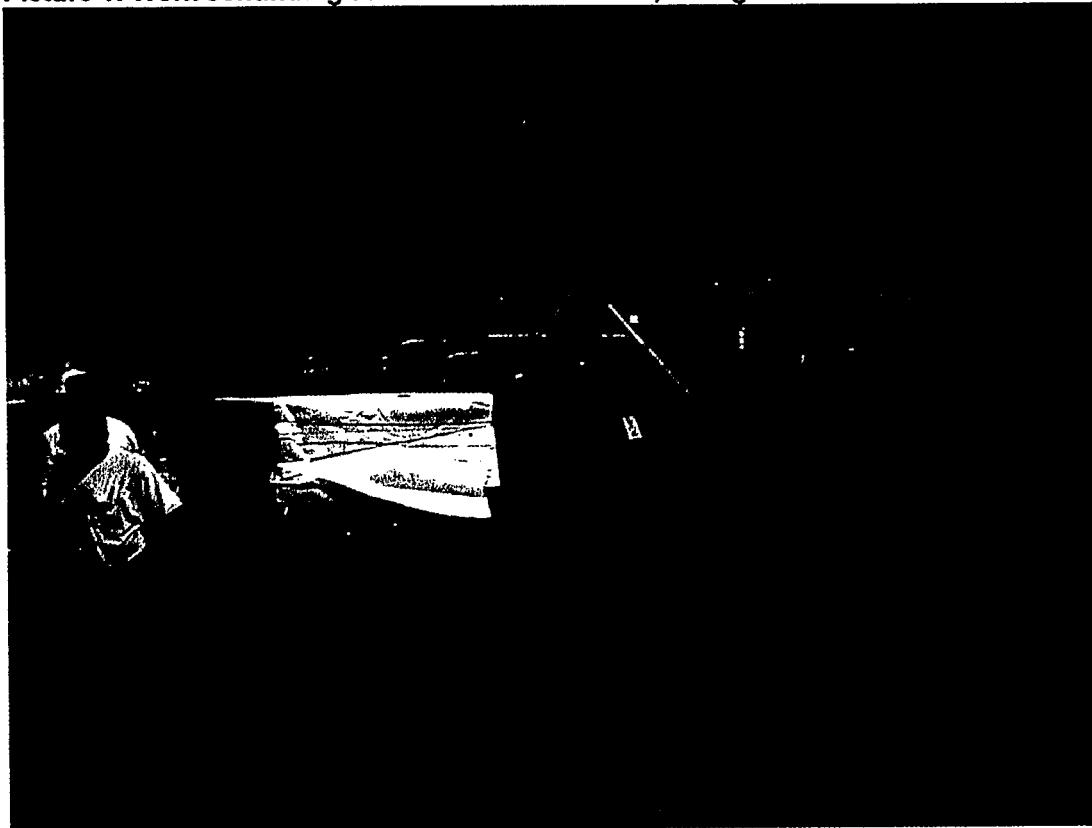

$$SOR = \frac{[Cs-137]}{23} + \frac{[Sr-90]}{15} + \frac{[Ra-226]}{5} + \frac{[Co-60]}{1160} + \frac{[Am-241]}{40} + \frac{[Pu-238]}{66} + \frac{[Pu-239/240]}{40}$$

Uranium and thorium isotopes were ignored in this comparison since none of their concentrations exceeded expected background values for uranium in soil, and it is not desired to remediate areas due to normally present natural isotopes. Strontium-90 was not analyzed for in this investigation because it has not been detected in any significant concentration in AOC 16, and since it was infrequently detected (2 samples of 13) at concentrations below 1 pCi/g during our investigation of the Pile Fan Sump removal (where significant quantities of Sr-90 were present). The sums of ratios for each sample are provided in the "AOC16 Summary Table" in the Appendix 2. Radium-226 results, even though a natural radionuclide whose concentration was detected at expected background levels, is included in the summary table because a cleanup goal for it is specified in the OU I ROD. However, all of the SOR's that exceeded unity were due only to high concentrations of cesium-137 in soil.

The samples obtained during the September survey showed that numerous locations had soil concentrations exceeding the cleanup goal by a substantial margin. The samples obtained in October showed the continued remediation of AOC 16 was productive and reduced both direct radiation readings and soil radionuclide concentrations. It is not expected that all soil concentrations will be below the cleanup goal in remediated Class 1 areas, and this was shown to be the case even after numerous efforts by BNL. This is the purpose of the elevated measurement comparison explained in MARSSIM, and discussed at the end of this report.

## CONCLUSION

Based on the survey and sample results of September, numerous small areas of elevated activity remained after the initial remediation attempt by BNL. A few areas with concentrations slightly over the cleanup goal were detected during the second survey in October. It is not necessary to remediate an area so that every conceivable sample will be below the cleanup goal, since this goal is based on a large-area average concentration. However, those areas exceeding the cleanup goal must be compared using area factors and the elevated measurement comparison test in MARSSIM to see if they are statistically significant enough to cause the failure of the survey unit.

Elevated measurement comparisons (EMC's) were provided by BNL and will be included in the Completion Report for AOC 16. The two elevated samples obtained in October, samples 101101 and 101107, meet these tests for remaining contaminated areas up to 16 square meters in size. Neither of these samples were obtained from contaminated areas of that extent, in fact, the contamination was only identified in one or two square meters. Therefore, AOC 16 was found to meet cleanup goals within the statistical boundaries identified in MARSSIM.

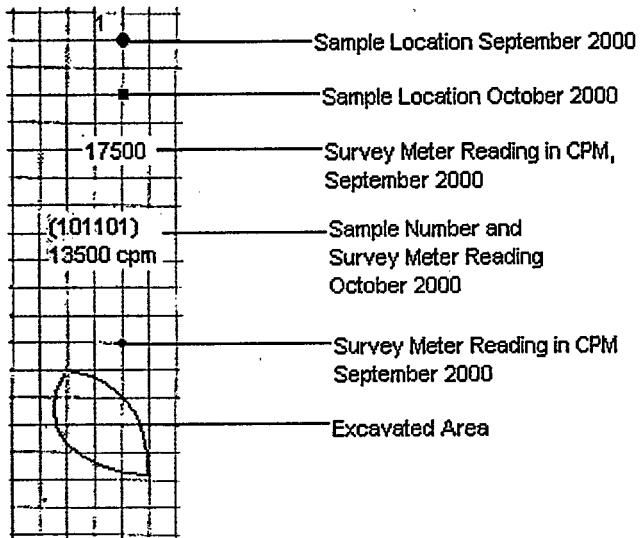

The verification surveys performed for AOC 16 underscore the importance of 100% walkover surveys in identifying small but elevated zones of soil contamination. Once the actual soil concentrations are obtained by analysis, areas with concentrations exceeding the cleanup goal need to be compared using the EMC test in MARSSIM to determine if any additional action is required. The boundaries for this comparison should be established within the Sample and Analysis Plan for the project.

ANALYTICAL METHODS

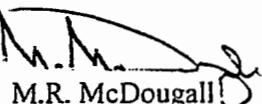

Americium-241 was analyzed using Method EML Am-01 modified. Isotopic Plutonium was analyzed using Method EML Pu-02 modified. Isotopic Uranium was analyzed using Method EML U-02 modified. Gamma Spectroscopy was performed using Method LANL ER-130 modified.

PROBLEMS OR UNUSUAL CIRCUMSTANCES

No problems or unusual circumstances were noted during the analytical process.

CERTIFICATION OF ACCURACY

I certify that this data report is in compliance with the terms and conditions of the Purchase Order, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hard copy data package has been authorized by the cognizant project manager or his/her designee to be accurate as verified by the following signature.
