1.0 INTRODUCTION

This report documents the Operation and Maintenance (O&M) activities undertaken during calendar year 2004 for the Current Landfill and the Former Landfill Areas (Former Landfill, Interim Landfill, and Slit Trench). Brookhaven National Laboratory (BNL) is responsible for performing this work to comply with the post-closure O&M requirements specified in 6 New York State Code of Rules and Regulations (NYCRR) Part 360, Solid Waste Management Facilities, effective December 31, 1988. The details of the O&M programs are described in the Final Operations and Maintenance Manuals for the Current Landfill (CDM Federal, 1996a) and the Former Landfill Areas (CDM Federal, 1996b).

The following are the primary objectives of the O&M program:

- Monitor the effectiveness of the impermeable caps in protecting groundwater quality;
- Monitor the potential generation and migration of soil gas; and
- Maintain and monitor the various components of the closure system (landfill caps, drainage structure, and environmental monitoring systems).

This is the ninth year of O&M for the Current Landfill, the eighth year for the Former Landfill and Slit Trench, and the seventh year for the Interim Landfill.

1.1 Site Description and Project Background

BNL is a 5,265-acre site located in central eastern Long Island, New York. The facility is a federally owned and funded international research and learning center managed, by Brookhaven Science Associates (BSA) under contract with the United States Department of Energy (DOE). On December 21, 1989, the site was placed on the United States Environmental Protection Agency's (USEPA's) National Priorities List (NPL), a ranking of hazardous waste sites compiled by the federal government as part of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA). Placing BNL on the NPL resulted in the establishment of a remediation-

task list for various locations around the facility. The site subsequently was divided into seven (7) separate remediation work areas known as Operable Units. The Current Landfill and Former Landfill Area are located in Operable Unit I (OU I), near the south central portion of the BNL site (see Figure 1).

Current Landfill (CLF) The Current Landfill consists of one unlined waste-cell that was operated from the late 1960s until the mid 1980s for disposing of waste generated at the Laboratory. An impermeable cap covering the cell was completed in November 1995. Additional information about the cap's construction can be obtained from the *Construction Certification Report for the Current Landfill* (CDM Federal, 1996b). Following the installation of the cap, the post-closure groundwater-monitoring program was implemented in December 1996, in accordance with 6 NYCRR Part 360 section 2.15, Solid Waste Management Facilities (effective December 31, 1988).

Groundwater quality near the Current Landfill is monitored under the O&M program for a wide variety of volatile organic compounds (VOCs), metals, radiological and water chemistry (landfill leachate) parameters. Monitoring in this vicinity was expanded in 1999 to include a wetland area adjacent to the landfill's eastern boundary. This area, known as the Wooded Wetland area, is a two-acre wetland located between the Former Hazardous Waste Management Facility (HWMF) and the Current Landfill. The wetland receives surface runoff from the Current Landfill, and usually is flooded during the spring/early summer, and dry in late summer/fall. Monitoring of the Wooded Wetland area has been incorporated into the Current Landfill Monitoring Program and consists of sampling and analyzing surface water and sediment to evaluate the potential for leachate migrating into this area, as originally performed under the *OU I Ecological Risk Assessment* (CDM Federal, 1999).

As required under 6 NYCRR Part 360, groundwater quality must be monitored for a minimum of five years, after which the permittee may request modification of the sampling and analysis requirements. In October 2001, BNL submitted the first *Five-Year Evaluation Report for the Current Landfill* (BNL, 2001). This report assessed groundwater trends over the five years after capping, and proposed changes to the sampling program. These changes were implemented in

CY02. Additional proposed sampling program modifications for CY04 are included as part of this annual report. Recommendations from the 2003 report were implemented in 2004.

Former Landfill (FLF) The Former Landfill Area encompasses three closely located landfill units; the Former Landfill, the Slit Trench, and the Interim Landfill. The Former Landfill is an unlined waste-disposal area originally used by the United States Army in the 1940's. Waste disposal operations ceased in 1966, and the landfill was covered with soil. The Interim Landfill also is unlined, and was reportedly used for approximately one year between the time the Former Landfill was closed, and the Current Landfill was opened. The Slit Trench is unlined as well, and believed to have been operated between 1960 and 1967 for disposal of construction and demolition debris (CDM Federal, 1996).

The Former Landfill and Slit Trench were capped in November 1996 and the Interim Landfill was capped in October 1997. Additional information about the construction of the caps can be found in the *Construction Certification Report for the Former Landfill* (Roy F. Weston, 1997) and the Interim Landfill (PW Grosser, 1997). BNL started O&M activities in December 1996 at the Former Landfill and Slit Trench, and in November 1997 at the Interim Landfill. Under this O&M program, groundwater quality in downgradient wells in the vicinity of the Former Landfill is monitored for VOCs, metals radionuclides and landfill-leachate parameters.

In March 2002, BNL submitted a Five-Year Evaluation Report for the Former Landfill (P.W. Grosser, 2002), which assessed trends in groundwater quality over the 5-year period following capping. Modifications to the sampling program are included annually as part of this report. Recommendations from the 2003 report were implemented in 2004.

1.2 Overview of the Monitoring Program

Groundwater Monitoring

Data quality objectives (DQOs) for each of BNL's groundwater monitoring programs are presented in the BNL Environmental Monitoring Plan (BNL, 2002). The design of the data-collection network was optimized as part of the process. Such optimization continues annually as part of the O&M program and is based on the interpretation of new data as well as historical trends. The primary decision identified for the landfill monitoring programs was "Are the controls effectively improving groundwater quality below and downgradient of the landfill?"

Groundwater samples are collected from monitoring wells positioned upgradient and downgradient of each landfill area. Analytical data are reviewed, and determinations are made regarding the effectiveness of landfill controls. Proposed modifications to sampling frequencies and analytical parameters are summarized in Section 6 of this report.

The monitoring program for the landfill areas consists of:

Soil Gas Monitoring. Measurements of methane, Lower Explosive Limit (LEL), and hydrogen sulfide are taken quarterly from numerous monitoring locations surrounding the landfills to evaluate the movement of soil gas from the landfills.

Wooded Wetland Monitoring. Surface waters and sediments in the wooded wetland adjacent to the eastern boundary of the Current Landfill are sampled annually to evaluate possible effects of landfill leachate on Tiger Salamander habitats. This work was incorporated into the routine landfill monitoring program, and is carried out annually (See Appendix A).

Routine Visual Inspection, Maintenance, and Repair. Monthly inspections are performed to monitor the structural and/or operational status of the landfill caps, drainage structures, and environmental monitoring systems.

Leachate Discharge. Visual inspections of the landfills are performed monthly to monitor for signs of leachate discharge. If observed, samples of the leachate are collected and

analyzed.

These activities are discussed in greater detail in Sections 2 through 5 of this report. Section 6 contains the conclusions and recommendations. References are included in Section 7.

2.0 GROUNDWATER MONITORING

2.1 Monitoring Well Networks

Current Landfill

Since February 1996, groundwater quality at the Current Landfill has been monitored using ten downgradient wells and one background monitoring well. Figure 2 depicts the location of the monitoring wells. Figure 3 shows the water table contours for December 2004. The depths of the screen intervals for the Current Landfill wells are listed below.

Well ID	Screen Interval (feet BLS)
087-09*	24-34
087-11	11-21
087-23	25-40
087-24	70-80
087-26	70-80
087-27	5-20
088-109	6-21
088-110	10-25
088-21	5-20
088-22	70-80
088-23	120-130

*Background well

BLS - Below Land Surface

Former Landfill

Since January 1997, groundwater quality at the Former landfill area has been monitored using eight shallow monitoring wells (3 upgradient and five downgradient). The locations of the eight

monitoring wells are presented in Figure 4. The direction of groundwater flow in the Operable Unit I area of the site is generally to the south-southeast. Figure 3 shows the December 2004 water table contours for the area. The screen zones for Former Landfill wells are summarized below.

Well ID	Screen Interval (feet BLS)
086-42*	65-75
086-72*	41.5-56.5
087-22*	43-53
097-17	29-39
097-64	29-44
097-277	40-55
106-02	55-65
106-30	29-44

BLS - Below Land Surface

2.1.1 Sampling Frequency and Analytical Parameters

Monitoring wells at both landfills were sampled in 2004 during the following periods:

Sampling Event	Sampling Dates
Round 1	January 13 and March 9
Round 2	May 5 - 9
Round 3	August 3 - 4
Round 4	November 17 - 18

Dvirka and Bartilucci Consulting Engineers, Woodbury, New York conducted the groundwater sampling and General Engineering Labs, Inc. and Severn Trent Laboratories, Inc analyzed the samples. See Table 1 for a summary of analyses performed by well and sampling round.

2.1.2 Quality Assurance / Quality Control

The groundwater samples were collected and analyzed in accordance with strict quality assurance, quality control (QA/QC) requirements as described in the BNL Groundwater Monitoring Program Quality Assurance Project Plan (QAPP) (BNL, 1999). The analytical results for groundwater samples collected during 2004 satisfied the data-quality objectives. The sampling team personnel are responsible for assuring that a master calibration/maintenance log is maintained for each field-measuring device (e.g., pH conductivity, turbidity meters e.g.). The sample coordinator provided a calibration/maintenance log for equipment supplied to the contractor's sampling teams.

The analytical results of samples collected for the Current and Former Landfill projects underwent data verification, using BNL standard operating procedures EM-SOP-203, Chemical Data Verification and EM-SOP-204, Radiochemical Data Verification. These procedures are designed to verify the accuracy and/or completeness of analytical data. The data-verification process is implemented to detect the most common analytical problems that affect the quality of the results. To accomplish this task, QA/QC items such as the following were checked: holding times, matrix spikes, laboratory and field blanks, and field logs. If items are found that can affect the use and interpretation of the data, they are either corrected, as in the case of unreadable information on the field logs, or the data is qualified, as in the case of contamination of the blanks or violations of the holding time.

Guidance on the collection of QA/QC samples is contained in the QAPP, and in BNL procedure EM-SOP-200 "Collection and Frequency of Field Quality Control Samples". The QA/QC samples collected included trip blanks, field blanks, matrix spike/matrix spike duplicate (MS/MSDs), and blind duplicates.

Trip blanks were analyzed for aqueous VOCs only. One trip blank was shipped to the analytical laboratory with each set of samples submitted for VOC analyses. One duplicate sample was collected during the first and third quarters when only the Current Landfill was sampled and two duplicate sample were collected during the second and fourth quarters when both landfills were

sampled. No errors were detected in the duplicate analyses. Matrix spike/matrix spike duplicates (MS/MSDs) samples were collected at a frequency of two MS/MSD samples per quarter. This ensures that the matrix of the sample does not adversely impact the analysis. In March, cyanide, total kjeldahl nitrogen (TKN) and iron reported recoveries below QC limits. In May, recoveries below QC limits were reported for ammonia, TKN, and thallium. In August, nitrite and iron reported recoveries below QC limits. In November, iron, lead, manganese, silver, thallium and TKN had recoveries reported below QC limits. Associated results for these analytes in the associated samples were qualified as estimated. Several VOCs had recoveries below QC limits in March, May, and November. These results were not significant and did not result in any qualification to the data.

2.2 Landfill Groundwater Monitoring Results

This section summarizes the results for VOCs, metals, water-chemistry parameters, and radionuclides detected for both the Current Landfill and Former Landfill in calendar year 2004. The historical trends in concentrations of key contaminants are assessed and shown graphically in Figures 5 through 12. Summary tables of all 2004 landfill groundwater data are presented in Tables 2 through 9. Detections that exceed groundwater standards are highlighted. The summary tables include groundwater standards, laboratory results, minimum detection limits, and laboratory data qualifiers.

The groundwater standards used for evaluating groundwater data include those contained in the NYSDEC Ambient Water Quality Standards and Guidance Values (June 1998, with addendums April 200 and June 2004). Groundwater standards for radiological compounds were supplemented with New York State Department of Health's (NYSDOH's) standards for drinking water when a NYSDEC groundwater standard was not available. When there were no groundwater standards for a radiological compound, a Groundwater Screening Level was used. This value is based on a dose equivalent of 4 mrem/year and was calculated as 4% of the USDOE Derived Concentration Guides (DCG) (DOE Order 5400.5) for the isotope of concern. These values are listed under the "groundwater standards" column in the summary tables and annotated where appropriate. Laboratory results that exceed the groundwater standards are highlighted in the data summary tables to facilitate review of the information.

The laboratory data qualifiers included in the summary tables vary for the different analyses. Explanations for the most commonly used laboratory data qualifiers are included in the notes in each summary table. Complete 2004 laboratory data reports, chain of custody forms, and well-sampling logs for both landfills are archived and available upon request. In addition, analytical results are stored in the BNL Environmental Information Management System (EIMS) database.

2.2.1 Current Landfill

2.2.1.1 Volatile Organic Compounds (VOCs)

Benzene, and/or chloroethane, were detected above their respective groundwater standards in four of the ten-downgradient monitoring wells during 2004 (Table 2). Along with 1,1-dichloroethane, these VOCs have historically been the primary groundwater contaminants detected downgradient of the Current Landfill.

Figure 5 plots the concentration trends of total VOCs (TVOC), benzene and chloroethane. As shown, VOCs remained relatively stable at low concentrations. Overall, the trend plots also show a distinct decrease in VOC concentrations from the high concentrations seen prior to the installation of the cap. This reflects the positive effects of the capping on the groundwater quality downgradient.

Benzene exceeded the 1 µg/L standard in wells 087-11, 087-23, and 087-27. Chloroethane exceeded the 5 µg/L standard in wells 087-11, 087-23, 088-109, and 088-110. The maximum chloroethane concentration was 29 µg/L in well 088-109; which is a significant decrease from the previous years high value of 77 µg /L. Benzene was detected at a maximum of 6.6 µg/L in well 087-11. There have been no detections of VOCs exceeding groundwater standards in wells 087-24, 088-22, and 088-23 since 1998. These downgradient wells are screened in the mid-to deep-Upper Glacial Aquifer as perimeter wells to monitor the vertical extent of contamination from the Current Landfill. No VOCs were detected in the background well.

2.2.1.2 Water Chemistry Parameters

Groundwater samples near the Current Landfill were analyzed for ammonia, total kjeldahl nitrogen (TKN) cyanide, sulfate, nitrite, nitrate, total nitrogen, chloride, alkalinity, total dissolved solids

(TDS or residue, nonfilterable) and total suspended solids (TSS or residue, filterable), during 2004 (Table 1). The results are provided in Table 3. Elevated levels of these parameters can be indicative of the presence of landfill leachate.

Ammonia was the only compound detected above the standard of 2 mg/L, with exceedances in three downgradient wells (087-11, 087-27, and 088-110) during four sampling events as shown in Table 3. The highest concentration of 8.5 mg/L was reported for well 087-11 in January. The highest level observed during 2004 in background well 87-09 was 0.51 mg/L. With the exception of the January result from well 087-11, the levels of ammonia detected seem to have stabilized from their pre-cap highs.

During 2004, all sulfate and chloride concentrations remained below the groundwater standard of 250 mg/L. The highest sulfate value reported for 2004 was detected in the November sample from monitoring well 088-110, at a concentration of 29.3 mg/L.

Chloride concentrations ranged from 3.8 mg/L in well 087-27 during May, to a high of 53.7 mg/L in well 087-09 in January. Chloride concentrations historically have been significantly below the groundwater standard of 250 mg/L in all Current Landfill wells. Figure 6 plots these trends, showing the low and stable nature of chloride concentrations in the vicinity of the Current Landfill.

Alkalinity, in the form of bicarbonate, is the concentration of anions available to neutralize acid, and is often used as an indicator of leachate contamination. The alkalinity in background well 087-09 ranged from 16 mg/L to 26 mg/L during 2004. The highest alkalinity concentration during 2004 was detected in downgradient, shallow Upper Glacial Aquifer well 087-11, at 223 mg/L in January. There is no groundwater standard for alkalinity. The concentration trends plotted in Figure 6 show an overall decrease in alkalinity following the capping of the landfill. Alkalinity levels in the background well remained stable during this period.

TDS and TSS results were similar to those from previous years, and indicate some continuing movement of leachate from the Current Landfill as evidenced by comparing data from downgradient

and background wells. TDS and TSS concentrations in background well 087-09 ranged from 97 mg/L to 416 mg/L, and 4 mg/L to 16 mg/L, respectively. The maximum concentrations observed in downgradient wells were 10,200 mg/L and 144 mg/L of TDS and TSS, respectively.

No water chemistry parameters have exceeded groundwater standards in downgradient wells 087-24, 088-22, and 088-23, since 1998. These wells are all screened in the mid to deep-Upper Glacial Aquifer to monitor the vertical extent of contamination from the Current Landfill. A comparison of downgradient and background wells shows that leachate continues to be generated from the Current Landfill, albeit at low concentrations. Decreasing trends in concentration indicate that the capping is effectively reducing the generation and migration of leachate.

2.2.1.3 Metals

Historically, iron and manganese were detected consistently above groundwater standards in the majority of wells surrounding the landfill. While these metals indicate the presence of leachate, the groundwater standards for these compounds are considered secondary standards based on aesthetics and taste rather than risk to human health. Precipitated iron from the BNL Water Treatment Plant was disposed of at the Current Landfill during past operations. The highest concentrations generally are found in the shallow wells 87-11 and 87-27, located immediately south of the Current Landfill (see Figure 7). There have been no detections of metals, other than iron and manganese, exceeding groundwater standards in wells 087-24, 087-26, and 088-23 since 1998. These wells are all screened in the mid-to-deep Upper Glacial Aquifer to monitor the vertical extent of contamination from the Current Landfill. Concentrations in upgradient well 87-09 still are lower than in the downgradient wells, suggesting continued leachate migration from the landfill. Given the relatively short time that the landfill has been capped, the anticipated transport time of groundwater from the north end of the landfill to the downgradient monitoring network, and the disposal of sludge containing metals during the landfill's operation, the continued presence of iron, magnesium and sodium in these wells is not unexpected.

During 2004, iron, manganese, and sodium continued to be detected above their respective groundwater standards (Table 4). Iron in the downgradient wells peaked at a maximum of 83,000

µg/L in well 087-23 during August. In contrast to background concentrations, in well 87-09, iron ranged from 3,600 µg/L to 8,320 µg/L. Manganese ranged from 34.5 µg/L to 867 µg/L in background well 087-09, and up to 9,380 µg/L in the downgradient wells. Background sodium levels ranged from 17,100 to 36,100 µg/L; whereas downgradient levels ranged up to 29,000 µg/L. The proximity of well 087-09 to Brookhaven Avenue and the affects of road salting in the winter may be contributing to the higher values. Arsenic was reported above the standard of 10 µg/L in wells 087-23, 088-109, and 088-22 at concentrations up to 35.4 µg/L . Arsenic detections have historically been observed at similar levels in Current Landfill wells. [d1]

2.2.1.4 Radionuclides

No radionuclides were detected above groundwater standards during 2004 (Table 5). Strontium-90 and tritium were the only radionuclides detected during 2003. Low levels of strontium-90 were detected in upgradient well 87-09 and in downgradient wells 087-11, 087-27, 088-109, 088-110, and 088-21. Concentrations were well below the 8 pCi/L groundwater standard, and ranged from 0.51 pCi/L in well 088-109 to 1.9 pCi/L in well 088-21. Overall, strontium-90 concentrations have shown either decreasing or stable trends, with concentrations at or near the detection limit (Figure 8). Gross beta activity, which is a possible indicator of strontium-90 in groundwater, ranged from 1.03 pCi/L in well 087-11 to 8.1 pCi/L in well 087-11.

Tritium was detected significantly below the groundwater standard of 20,000 pCi/L with a maximum value of 820 pCi/L in shallow downgradient well 087-26 (Figure 8). Tritium and Sr-90 concentrations have not exceeded groundwater standards in wells 087-24, 088-22, and 088-23 since 1998. These wells are all screened in the mid-to-deep-Upper Glacial Aquifer to monitor the vertical extent of contamination from the Current Landfill.

2.2.2 Former Landfill

2.2.2.1 VOCs

During 2004 there were no detections of VOCs above groundwater standards in wells in the Former Landfill Area (Table 6). The compounds consistently found in the Former Landfill monitoring wells include 1,1,1-trichloroethane, 1,1-dichloroethane, and chloroform. Chloroform was reported in

several wells during the year at concentrations ranging from 0.29 µg/L to 1.9 µg/L, well below the groundwater standard of 7 µg/L. 1,2,4-Trichlorobenzene was also detected in one well, 086-72 at an estimated concentration of 0.22 µg/L .

Figure 9 shows plots of the historical VOC detections for the Former Landfill monitoring wells. During 2004, VOCs were detected at the Former Landfill in several wells, but only at trace concentrations, indicating that the cap on the landfill is operating as intended.

2.2.2.2 Water Chemistry Parameters

Groundwater samples from monitoring wells in the Former Landfill Area were analyzed for sulfate, nitrite, nitrate, total nitrogen, chloride, alkalinity, TDS (TDS or residue, non-filterable) and TSS (TSS or residue, filterable). During 2004, none of the of water chemistry parameters exceeded applicable groundwater standards (Table 7). In general, all of the landfill leachate indicator parameters were relatively low concentrations in comparison to background, and displayed either decreasing or stable trends in 2004. These trends indicate that the landfill cap is effective.

Sulfate concentrations ranged from 10.1 mg/L to 12.6 mg/L in the background wells, and from 8.9 mg/L to 20.5 mg/L in downgradient wells, significantly below the standard of 250 mg/L. Nitrogen in the form of nitrate (NO_3), and chloride were consistently low, with levels in the downgradient wells nearly indistinguishable from those in the background wells. Chloride concentrations ranged from 3.0 mg/L to 17.3 mg/L, well below the groundwater standard of 250 mg/L. The trends plotted in Figure 10, indicate chloride concentrations are stable over time.

Detections of alkalinity ranged from 5.5 mg/L to 13 mg/L in background wells and from 6 mg/L to 30 mg/L in downgradient wells. The trends plotted in Figure 10**,** demonstrate the alkalinity concentrations in 2004 are generally consistent with 2003 levels. The concentrations are approaching background, and suggest a gradual decline in the release of landfill leachate since the landfill was capped.

TDS concentrations ranged from 35 mg/L to 53 mg/L in the background wells and from 31 mg/L to 70 mg/L in the downgradient wells. TSS concentrations were from 2 mg/L to 6 mg/L in the background wells, and from 1 mg/L to 5 mg/L in the downgradient wells.

Nitrite, ammonia, and TKN were not detected in the Former Landfill monitoring wells during 2004.

2.2.2.3 Metals

Only two wells had detections of metals that exceeded the groundwater standards during 2004 (Table 8). Well 097-17 had metal concentrations exceeding groundwater standards for aluminum, iron, and thallium (708 µg/L , 1,050 µg/L , and 0.69 µg/L , respectively). Well106-02 had a thallium detection of 0.54 µg/L which is above the groundwater standard of 0.5 µg/L . These results are consistent with historic detections.

2.2.2.4 Pesticides/PCBs

There were no detections of pesticides or polychlorinated biphenyls (PCBs) during 2004. The sampling results are summarized in Table 9.

2.2.2.4 Radionuclides

There were no detections of radionuclides above the groundwater standards during 2004. The sampling results are summarized in Table 10, and concentration trend plots are shown on Figure 12.

Strontium-90 was detected in downgradient well 097-64, at an estimated concentration of 3.85 pCi/L, which is well below the standard of 8 pCi/L. Tritium was detected in upgradient well 86-42 at very low levels in each of the two sampling rounds with a maximum concentration of 770 pCi/L. Tritium was not detected in any other Former Landfill monitoring wells.

Radionuclide detections in 2004 continued to be stable and significantly reduced from historical high levels.

3.0 Wooded Wetland Monitoring

Sampling at the Wooded Wetland is performed as part of the compliance monitoring for the Current

Landfill. Prior to the capping of the Current Landfill, leachate was periodically observed in the wetland. The monitoring is focused on metal concentrations in the sediment and surface water to evaluate potential risks to the local Tiger Salamander population. See Appendix A for a detailed discussion of the sampling and analysis results.

Sediment

Sediment samples were collected from the Wooded Wetland Area in May 2004. The concentrations were compared to the maximum sediment concentrations reported in the ecological risk assessment (Appendix A, Table 5). The results suggest there is no elevated risk to adult salamanders from sediments in the Southern or the Northern Ponds. The results for 2004 indicate that metals concentrations in sediments are less than the maximum concentration benchmarks for copper, lead, manganese, mercury and zinc (See Appendix A, Tables 2A and 2B). The maximum doses from exposure to these sediments result in a hazard quotient that is less than 1.0. In addition, because concentrations of metals were not detected above BNL background in all but one location (sediment sample location SD-5 had a manganese concentration of 109 mg/kg, exceeding the background concentration of 84.3 mg/kg), the metals are not considered a potential risk.

Surface Water

Surface water samples from the Southern and Northern Ponds had average iron concentrations of 1,114 µg/L and 706 µg/L , respectively. Although the average concentration from the Southern Pond was higher than the 1,000-µg/L critical toxicity concentration (Appendix A, Table 2B), it was lower than the BNL background concentration of 1,990 µg/L .

In 2003, the average surface water concentration of aluminum (1,865 µg/L) was above the critical water concentration (525 µg/L) in the Northern Pond. During the 2004 sampling event, the average aluminum concentration fell to 170 µg/L . With the exception of iron in the Southern Pond, all average metals results were below the critical water concentration during 2004.

Based on the 2004 sampling results, annual sampling of the Wooded Wetlands should continue as

part of the annual O&M landfills monitoring activities for at least another year. A complete copy of the 2004 Annual Wooded Wetlands Report is included in Appendix A of this report.

4.0 SOIL GAS MONITORING

4.1 Soil Gas Monitoring Networks

Soil gas readings were collected from wells surrounding the Current and Former Landfills in March - June, October, and November 2004. Methane, lower explosive limit (LEL), and hydrogen sulfide were measured using a Landtec GA-90 (Serial # 690). The LEL for methane is 5.3% and the upper explosive limit (UEL) is 15%.

4.1.1 Current Landfill

Along the perimeter of the Current Landfill, 58 points were sampled for soil gas. The sampling points include 12 soil-gas well clusters consisting of three sampling intervals per cluster, and 11 soil-gas well couplets consisting of two sampling intervals per couplet. Table 11 describes each soil-gas well. Their locations are illustrated on Figure 13.

4.1.2 Former Landfill Area

Twenty-four sampling points were monitored for the Former Landfill Area. These points include six well couplets consisting of two sampling points per couplet. Details of each soil gas well are given in Table 11 and their locations shown in Figure 14.

4.1.3 Sampling Frequency

Soil-gas was monitored for each landfill on the following dates.

Sampling Event	Current Landfill	Former Landfill
Round 1	March 2004	March 2004
Round 2	June 2004	June 2004
Round 3	October 2004	October 2004
Round 4	November 2004	November 2004

4.2 Results of Soil-Gas Monitoring

Action levels for soil gas are specified in 6 NYCRR Part 360-2.17(f) in terms of percent LEL, which is primarily related to the amount of methane present. This discussion focuses primarily on the methane levels detected during quarterly monitoring. Hydrogen sulfide is monitored, but has no

regulatory action level. 6 NYCRR Part 360-2.17(f) specifies that active measures to control decomposition gases are required when the concentration of methane or other explosive gases exceeds 25 percent of the LEL (or 1.3% methane) in facility structures, or 100 percent (%) of the LEL (or 5.3% methane) at the site boundary.

4.2.1 Current Landfill

A total of 23-soil gas monitoring well clusters are positioned around the Current Landfill (Figure 13). Potential receptors, or areas where methane can accumulate in the vicinity of the Current Landfill, include the National Weather Service building located 480 feet north northwest of the Current Landfill on the north side of Brookhaven Avenue. Should methane extend to the south side of Brookhaven Avenue, active measures will be required to control its migration. Four outpost soil gas wells, GSGM-1 to GSGM-4, located along the south side of Brookhaven Avenue are used to monitor the northern extent of migration of landfill gas.

The results of the soil gas monitoring for 2004 are summarized in Table 12. Appendix B contains the field notes recorded during the sampling events. Instrument measurements show that methane continues to be generated in several areas of the landfill. The percent of the LEL is equivalent to 20 times the methane concentrations in the landfill and is elevated along the northwest corner and the south boundary of the Current Landfill. The highest levels were recorded in well cluster SGM-3 (ranging from 0 % of the LEL to 1,042 % of the LEL) and in well cluster SGM-4 (ranging from 36 % of the LEL to 1,014 % of the LEL) located along the western boundary. These levels have remained stable since 1996 when monitoring began and the current gas venting system appears to be controlling gas accumulation. These data are consistent with previous years (see Appendix D).

Outpost wells, GSGM-1 to GSGM-4, located along the south side of Brookhaven Avenue showed no methane during 2004, indicating that the methane accumulation and migration does not extend to this area. Should methane extend to the south side of Brookhaven Avenue, active measures will be required to control its migration.

Hydrogen sulfide is a product of anaerobic decay in landfills and can produce an odor like rotten eggs. It is a nuisance, but rarely a toxicity problem. For reference, the National Institute of Occupational Safety and Health sets an exposure limit of 10 parts per million (ppm) hydrogen sulfide in the breathing zone for an 8-hour period.

Field notes indicate that the sampler believed that the hydrogen sulfide detector was not functioning properly during the March sampling event. Since three subsequent rounds of hydrogen sulfide were collected during 2004 and the parameter has no action level, the loss of one round of data does not adversely impact the overall monitoring program. While the results for March are presented in Table 12, they are not discussed further in this report. Hydrogen sulfide measurements collected from the soil gas monitoring wells ranged from 0 ppm to 21 ppm. Well SGM-12A located near the landfills southern section, had the highest hydrogen-sulfide concentration, which was above the 10 ppm exposure limit; however it was taken from a vapor point screened 2.5 - 7.5 feet below the surface and not from the breathing zone. Like methane, receptors to hydrogen sulfide are considered to be in areas such as basements where the gas can accumulate. Based upon the readings obtained from the outpost soil gas wells along the south side of Brookhaven Avenue (GSGM-1 – GSGM-4), there is no evidence that hydrogen sulfide is migrating toward the National Weather Service building.

4.2.1.1 Trend in Soil-Gas Data

Appendix D contains the results of methane monitoring for the Current Landfill from 1996 through 2004. Generally the levels of methane and hydrogen sulfide in the wells along the northwest landfill boundary and southeast corner have remained stable.

4.2.2 Former Landfill Area

A total of 12 soil gas monitoring well clusters are positioned around the Former Landfill areas. During 2004, the well clusters were monitored on a quarterly basis. The only existing operating facilities and offices within the immediate vicinity of the Former Landfill area are located approximately 620 feet to the west. However, because these facilities do not have basements, there is minimal potential for hazardous levels of landfill gases to accumulate in these structures.

Based upon the four sampling events, little to no methane or hydrogen sulfide was detected. Table 13 details the 2004 soil gas monitoring results for the Former Landfill Area. Appendix B contains the field notes recorded during the sampling events.

4.2.2.1 Trends in Soil-Gas Data

The results of monitoring the Former Landfill continue to be consistent with the initial survey of the methane- gas migration conducted in 1995, during which concentrations between 0% to 2% methane were recorded. Hydrogen-sulfide gas also was measured during this survey. Field notes indicate that the sampler believed that the hydrogen sulfide detector was not functioning properly during the March sampling event. Since three subsequent rounds of hydrogen sulfide were collected during 2004 and the parameter has no action level, the loss of one round of data does not adversely impact the overall monitoring program. While the March results are presented in Table 12, they are not discussed further in this report. The remaining hydrogen sulfide results showed concentrations ranging from 0 ppm to 2 ppm. Appendix D includes the results of monitoring methane in the Former Landfill Area for 1996 through 2004.

Presently, there is no measured pathway for methane-gas migration, nor do the concentrations represent an explosive hazard as shown by the non-detect readings on the LEL meter. The age of the Former Landfill and the types of materials disposed of would likely result in the low levels or absence of methane or hydrogen sulfide.

5.0 MAINTENANCE AND REPAIR

Monthly site inspections were performed by BNL at the Current and Former Landfill areas to monitor the structural and/or operational status of the landfill cap, gas vents, drainage structure, and environmental monitoring system (groundwater wells, soil gas wells) in general accordance with the approved O&M Manuals. A copy of the inspection reports is included in Appendix C. Maintenance and repair work completed or required by BNL is discussed below.

5.1 Landfill Cap and Gas Vents

The grass cover on the Former Landfill Area and the Current Landfill were maintained in accordance with the O&M Plan (CDM, 1996a and CDM 1996c). No gas vents at either landfill

required repair. Lawn mowing was undertaken at both the Former and Current Landfills and the levels in some areas was allowed to grow higher to improve vegetation that is intended to protect the liner material.

5.2 Drainage Structures

The drainage structures at both the Current and Former landfill areas were maintained and any obstructions removed. They were observed to be operational and structurally sound during the site inspections. Grass and small brush were weeded from the drainage channels several times during the year. Weeds and bush were treated with herbicides in areas of the channel that are difficult to weed. Other than routine grass trimming, no additional maintenance or repair work was required.

5.3 Environmental Monitoring System

The monitoring wells and soil gas monitoring wells associated with the landfills required no significant maintenance.

5.4 Related Structures

There are no structures, other than those mentioned in Sections 5.1 through 5.3 related to the landfills.

6.0 CONCLUSIONS AND RECOMMENDATIONS

6.1 Groundwater Monitoring

6.1.1 Conclusions for the Current Landfill

- VOCs such as benzene, and chloroethane continue to be detected in downgradient wells 087-11, 087-23, 087-27, 088-109, and 088-110 at concentrations above groundwater standards. The maximum VOC concentration (chloroethane) in 2004 was 29 µg/L in well 088-109. TVOC concentrations in these five wells have ranged between non-detect and 80 µg/L over the past several years indicating that low level VOCs continue to emanate from the landfill. The continued presence of leachate indicators is expected and normal, in view of the short time that the landfill has been capped, and the time needed for the transport of solutes from the upgradient end of the landfill to the downgradient monitoring network.

- Landfill water chemistry parameters and metals evaluated during the year suggest that leachate continues to emanate from the landfill. The continued presence of leachate indicators is expected and normal, in view of the short time that the landfill has been capped, and the time needed for the transport of solutes from the upgradient end of the landfill to the downgradient monitoring network.

- Tritium and Sr-90 continue to be detected in the wells downgradient of the Current Landfill, but at concentrations well below groundwater standards. These concentrations were consistent with those observed in 2003.

- Since 1998, there have been no detections of VOCs, metals, water chemistry parameters or radionuclides exceeding groundwater standards in wells 087-24, 088-22, and 088-23. These wells are all screened in the mid-to deep-Upper Glacial Aquifer to monitor the vertical extent of contamination from the Current Landfill.

- Although low levels of contaminants continue to be detected, the landfill controls are effective as evidenced by the improving quality of groundwater downgradient of the landfill.

- Sediment samples collected from the Northern and Southern Pond of the Wooded Wetland area are below the maximum sediment benchmark concentrations for the metals of concern. Since the hazard quotient is less than 1.0, there is no potential risk to the adult salamander populations from pond sediments.

- Iron concentrations detected in the surface water samples from the Southern Pond of the Wooded Wetland indicate a low potential for risk to larval salamanders since, the ratio of their concentrations in the water to the critical concentrations is greater than 1.0 but less than 10.

6.1.2 Recommendations for the Current Landfill

The groundwater monitoring program is adequate at this time. Since leachate is continuing to discharge from the Landfill, there are no recommended changes to the monitoring program.

6.1.3 Conclusions for the Former Landfill

- The Former Landfill is no longer a significant source of VOC contamination. No VOCs were detected above groundwater standards in 2004. VOC concentrations in the downgradient wells were at or near the minimum detectable limits.
- Landfill-leachate indicators in downgradient wells continue to be detected at concentrations above background, indicating some continued generation of leachate. However, the leachate concentrations are very low and remain stable. This low level of generation is expected, given the age of the landfill.
- The Former Landfill no longer appears to be a significant source of strontium-90 contamination. Strontium-90 was only detected in a single downgradient well (097-64), but at a concentration below the standard of 8 μg/L.
- The implemented landfill controls are effective, as evidenced by the improving quality of groundwater downgradient of the landfill.

6.1.4 Recommendations for the Former Landfill

The groundwater monitoring program is adequate at this time. Since leachate is continuing to discharge from the Landfill, there are no recommended changes to the monitoring program.

6.2 Soil Gas Monitoring

6.2.1 Conclusions for the Current Landfill

Methane and hydrogen sulfide levels in wells located along the northwest landfill boundary and southeast corner have remained stable and have not shown any significant increases or decreases over time. No significant gas migration has been observed at the outpost soil gas wells along Brookhaven Avenue.

6.2.2 Recommendations for the Current Landfill

The soil-gas monitoring program is adequate at this time, since methane gas is still being produced and leachate is continuing to discharge from the Landfill. If monitoring equipment fails during a sampling event, the sampling will be stopped and corrective action will be taken. Corrective action can include the repair of the equipment or obtaining new equipment. Once the corrective action is completed, the sampling event will continue.

6.2.3 Conclusions for the Former Landfill

Methane and hydrogen sulfide levels at the Former Landfill area continue to show little to no levels of landfill gasses.

6.2.4 Recommendations for the Former Landfill

There have been little to no detections of methane and/or hydrogen sulfide during monitoring at the Former Landfill over the past 6 years. If monitoring equipment fails during a sampling event, the sampling will be stopped and corrective action will be taken. Corrective action can include the repair of the equipment or obtaining new equipment. Once the corrective action is completed, the sampling event will continue.

6.3 Maintenance and Repair

Maintenance of the landfill caps will continue in accordance with the O&M requirements.

6.3.1 Current Landfill

Monthly inspections and maintenance will continue in accordance with the O&M requirements.

6.3.2 Former Landfill Area

Monthly inspections and maintenance will continue in accordance with the O&M requirements.

Operable Unit 1
Wooded Wetlands Supplemental Surface Water
and
Sediment Sampling and Analysis Report

ANNUAL WOODED WETLAND REPORT
2004

1.0 INTRODUCTION

This report summarizes and evaluates the annual sediment and surface-water sampling performed for Operable Unit I (OU I), Wooded Wetland area at Brookhaven National Laboratory, Upton, New York (BNL). The Wooded Wetland is located east of and adjacent to the Current Landfill and has the potential to receive leachate from the landfill. The wetland consists of a North and South pond. The annual sampling of the Wooded Wetland follows the recommendations of the Focused Ecological Risk Assessment Operable Units I/VI (CDM, 1999b). This report summarizes the results of the sampling conducted in accordance with the 1999 and 2000 OU I Wooded Wetlands Supplemental Sampling and Analysis Plans (BNL, 1999 and BNL, 2000). These plans were prepared as an addendum to the Sampling and Analysis Plan for the Remedial Investigation/Feasibility Study for Operable Unit I (SAIC, 1993).

The annual sampling focuses on analysis of metals in the sediment and surface-water to evaluate their potential risks to the local Tiger Salamander population. Seven sediment and seven surface-water samples were collected in May 2004 from two ponds (North and South), in the Wooded Wetland area, and analyzed for total metals.

1.1 Background

The Wooded Wetland is a two-acre area located between the Former Hazardous Waste Management Facility and the Current Landfill (Figure 1). The wetland receives surface runoff from the Current Landfill, which was capped in 1995, as well as land runoff from the south. The Wooded Wetland usually is flooded during the spring and early summer and dry in late summer. In the Current Landfill area, the water table is located approximately 10 to 15 feet below the Wooded Wetlands; therefore the wetland area does not receive groundwater recharge. High clay content of the near surface soils allows for perching of water from precipitation and runoff.

An ecological review and assessment of the wooded wetland is provided in the *OU I/VI Preliminary Ecological Risk Screening Report* (CDM, 1996b). As part of the Feasibility Study for OU I, a Focused Ecological Risk Assessment was conducted for this area of concern (CDM, 1999b).

Two surface-water samples (SW-4 and SW-5) and 14 sediment samples (SD-10 through SD-17) were collected from this area in 1994 during the OU I Remedial Investigation (CDM, 1996a). At six of the sediment locations, samples were collected from two intervals: 0 to 0.5 feet, and 1 to 1.5 feet. Samples were collected from the surface only at the remaining two locations (SD-10 and SD-11).

A gap was identified in the 1994 data set and supplemental sampling was carried out in December 1997 as part of the Ecological Risk Assessment. Only two surface-water and two sediment samples were collected and analyzed for metals during this sampling event due to the dry conditions at this time. Results from all four locations indicated lower concentrations of contaminants in both the

surface-water and sediment compared to the May 1994 locations. Figure 1 shows the benchmark 1994 and 1997 surface-water/sediment sample locations, respectively.

Samples of surface-water and sediment were collected at five locations in May 2004, as shown on Figure 2. These places were chosen based upon the locations where samples were collected in 1994 and 1997. Locations SW/SD-5 and SW/SD-6 were near to the two 1997 locations. SW/SD-17, SW/SD-12, and SW/SD-13 were close to three of the 1994 sediment sampling locations. Variability in sampling locations and number of samples were related primarily to seasonal drying of the ponds. Table 1 provides the sampling designation for comparison between samples taken each year since 1999.

The results of the surface-water samples from four of the locations (SW-17, SW-5S, SW-5N, and SW-E) indicated that the risk for larval salamanders was unlikely to low. At location SW-6, the concentration of metals in the surface-water sample indicated a moderate risk. Sediment results from the five locations indicated that the risk to adult salamanders is unlikely. (See the Ecological Risk Assessment, CDM, 1999b.)

In August 2000, four surface-water samples (2 from each pond), and seven sediment samples (4 from the South Pond, 3 from the North Pond) were collected from the Wooded Wetlands Area. The locations are shown in Figure 2. Background and maximum concentration values for sediment and water are presented in Tables 2A and 2B. From 2001through 2004 seven surface-water and sediment samples were taken from the ponds (Table 1). Analytical data for all years are provided in Tables 3 through 6. The following discussions focus on the findings of the 2004 sampling season.

2.0 GENERAL PROCEDURES

2.1 Environmental Sampling Procedures

Sampling was conducted by BNL on May 7, 2004, in accordance with the procedures and sampling locations outlined in the *OU I Sampling and Analysis Plan* (SAIC, 1993), supplementary Wooded Wetlands sampling plans (BNL 1999 and 2000) and BNL standard operating procedures for sampling surface-water and sediments.

Samples were sent to an off-site certified laboratory for analysis. They were submitted for total metals analysis, target analyte list (TAL) by EPA Methods 6010B, and mercury by EPA Methods 7470 and 7471. In accordance with the July 2000 Sampling and Analysis Plan, quality assurance/quality control samples included a blind duplicate (one per matrix), matrix spike/matrix spike duplicate (one per matrix), and, one equipment blank.

2.2 Criteria

To determine if sediment or surface-water concentrations pose a risk to tiger salamanders, analytical data were compared to benchmark sediment concentrations and critical water concentrations (Tables 2A and 2B) that were calculated in the *Ecological Risk Assessment* (CDM, 1999b). A benchmark sediment dose is a dose above which an observable toxic effect may occur in adult tiger

salamanders. Table 2A gives the benchmark sediment concentrations for five metals of concern. BNL background levels are higher than established Maximum Sediment Concentrations. Critical water concentrations are surface-water concentrations that have the potential to produce observable adverse effects to larval salamanders. The ten metals in the surface-water that have an estimated critical concentration, are summarized in Table 2B. Three of them have benchmark maximum concentrations greater than the critical levels.

2.3 Sample Locations

Seven sediment and seven surface-water samples were collected and analyzed for total metals in 2004 from the Northern and Southern Ponds. Four sediment and four surface-water samples were taken from the Southern Pond, and three sediment and three surface-water samples were collected from the Northern Pond. Table 1 lists 2004 samples with cross-references of the sampling locations to 1994, 1997, 1999, 2000, 2001, 2002 and 2003. Figure 2 shows the sediment and surface-water sampling locations.

3.0 SUMMARY OF ANALYTICAL RESULTS

The results from the total metals sample analyses of sediment and surface-water for each year are summarized in Tables 3 and 4, respectively. Tables 5 and 6 contain comparisons of average sediment and surface-water sample results for contaminants of concern to maximum contaminant and background concentrations, for each year.

3.1 Sediment

Table 5 summarizes the results for the contaminants of concern, specifically copper, lead, manganese, mercury and zinc, for the Northern and Southern Ponds. These results are compared with the maximum and background sediment concentrations from Table 2A.

To evaluate sediment concentrations in the Northern and Southern Ponds for the metals of concern, annual averages were calculated from the samples collected. The averages were determined to evaluate trends, since the sediment samples were grab samples collected from a number of locations.

The results from the four Southern Pond locations, SD-5, SD-6, SD-16, and SD-17, indicate that the concentrations of the metals of concern at these locations are below the maximum contaminant and background concentrations, with the exception of manganese taken at location SD-5. The average concentrations for metals of concern in 2004 are within the historic range seen in the Southern Pond and are below both the maximum and background sediment concentration values.

The 2004 concentrations of the metals of concern from the Northern Pond samples were similar to, or lower than, the maximum benchmark sediment concentrations. The average 2004 concentrations were also similar to, or less than previous 3 years levels. No significant trend in concentrations since 1999 is apparent.

3.2 Surface-Water

Table 6 presents the results of the ten metals of concern for each of the seven surface water samples collected during 2004. Also shown in Table 6, for comparison, are the surface water results from previous monitoring, along with the critical and benchmark water concentrations from Table 1B. Four surface water samples came from the Southern Pond (SW-5S, SW-6, SW-16 and SW-17) and three samples were collected from the Northern Pond (SW-4, SW-5N and SW-2001).

The Southern Pond samples show concentrations of aluminum above the critical concentration value at location SW-16. Values for iron were in excess of the critical concentration value at three of four locations (SW-5S, SW16 and SW17). Zinc concentrations were below the critical concentration value at all locations compared to being above the critical concentration value in 2003. Comparison of average values indicated that iron was the only metal of concern that was above the critical concentration value.

Aluminum and iron concentrations in the Northern Pond have historically been detected in excess of the critical threshold value. In 2004 no value was above the critical threshold value. With the exception of aluminum and iron, the average 2004 concentrations are similar to those in previous years.

4.0 CONCLUSIONS & RECOMMENDATIONS

The results of the May 2004 sediment and surface water sampling program indicate no elevated risk to adult salamanders from sediments in the Southern or the Northern Ponds when compared to the maximum benchmark concentrations (Table 2A). The sample concentrations for both ponds were lower than the maximum benchmark concentrations that would result in an elevated hazard quotient as discussed in the Final Focused Ecological Risk Assessment for OU I (CDM, 1999b). The potential risk is based on comparing the 2004 results with the maximum benchmark concentrations for copper, lead, mercury, and zinc. In addition, because concentrations were not detected above BNL background, they are not considered a potential risk. A hazard quotient greater than 1.0 but less than 10 is considered a low risk. When the averages of the parameters in the sediments collected during 2004 were used in evaluating potential risk, none of them were above the BNL background concentrations.

Surface water samples indicated an average iron concentration of 1,114 ug/l in the Southern Pond, which is higher than the 1,000 ug/l critical concentration. Although the iron concentration exceeded the background concentration in three of the seven samples in both ponds, the average concentration seen in the southern pond was within the historic range. The average iron concentration was below the critical concentration in the northern pond where historically it has been above this value. The average concentration of aluminum was below the critical water concentration (525 ug/l) in the both Southern and Northern Ponds where in the past it had been above the critical concentration in the Northern Pond. Zinc levels were below the critical water concentration (23.8 ug/l) in both ponds compared to being higher than this level in 2003.

There is a considerable amount of uncertainty reflected in deriving the critical water concentrations established in the Ecological Risk Assessment (CDM, 1999). This is largely due to the limited number of published toxicity values for the tiger salamander related to the metal of concern. In the case of aluminum, the critical water concentration is calculated by applying a correction factor of 0.1 (to account for uncertainty) to the mortality as indicated by the Lowest Observed Adverse Effects Level (LOAEL) for the mortality of the Jefferson salamander larvae. The Jefferson salamander larvae species is the closest match for the tiger salamander larvae. The critical water concentration for iron was taken from the EPA National Recommended Water Quality Criteria for Non-Priority Pollutants (EPA, April 1999). No maximum value is given under these criteria.

Overall, the results obtained from the May 2004 sampling indicates that most of the metals of concern in both sediment and surface-water are within the range of variability as compared to previous year values. The number of sediment and water samples collected from the Southern Pond in 2004 was the same as those collected in 2003, so the averages can be directly compared. No substantive effect due to leached metals from the landfill is evident in the sediments or surface-water.

In summary, the average values of the concentrations of the metals of concern in the sediments in either pond in 2004 were not above benchmark or BNL background concentrations. This indicates that a risk to adult salamanders is unlikely. The averages for the water samples collected from each pond in 2004 indicate that no metal of concern was above the critical concentration in the Northern

Pond and only aluminum was above the BNL critical water concentration in the Southern Pond. However, there is considerable uncertainty inherent in establishing the critical water concentration for aluminum in assigning the actual risk posed to tiger salamander larvae.

Based on the results of the 2004 sampling event, annual sampling of the Wooded Wetlands during the spring should continue for another year to document and confirm the trends monitored as part of the O&M Landfill Report.

NOTES:

1994 Samples were collected from 0.0 ' to 0.5'

Number in parenthesis ( ) indicates alternate identification for same location.

NA Not available

NS Not sampled

U Analyte was analyzed for but not detected.

N - Spike sample recovery was not within control limits

Table 3
Annual Wooded Wetland Report
Sediment Sample Results - Metals Analysis

LOCATION	CONTAMINANT	SAMPLES COLLECTED							
	Units : mg/Kg	1994	1997	Jun-99	Aug-00	Jun-01	May-02	May-03	May-04

J - Estimated value; concentration below method detection limit.

* - Duplicate precision is not within control limits.

B - Concentraion less than the contract required detection limit, but greater than or equal to the instrument detection limit.

NOTES:

1994 Samples were collected from 0.0 ' to 0.5'

Number in parenthesis ( ) indicates alternate identification for same location.

NA Not available

NS Not sampled

U Analyte was analyzed for but not detected.

N - Spike sample recovery was not within control limits

J - Estimated value; concentration below method detection limit.

* - Duplicate precision is not within control limits.

B - Concentraion less than the contract required detection limit, but greater than or equal to the instrument detection limit.
