BNL-2009

# Pulsed Magnet Design and Measurement Workshop

(Brookhaven National Laboratory, July 27-28, 2009)

## Attendees

- BNL NSLS-II: T. Shaftan, R. Heese, R. Fliller, G. Wang, S. Ozaki, G. Ganetis, I. Pinayev, A. Jain, D. Hseuh, S. Kowalski, M. Rehak, and S. Sharma.
- BNL NSLS: G. Rakowsky, and P. Zuhoski
- BNL CAD: A. Zhang
- BNL SMD: B. Parker
- SLAC: C. Burkhart, and A. DeLira
- KEK: A. Ueda, M. Shimada, and T. Miyajima
- TLS: J.-R. Chen, and C.-C. Kuo
- Duke University: S. Mikhailov
- Tokyo University: H. Takaki

## Pulsed Magnet Design and Measurement (PMDM) Workshop Schedule

Monday	27-July	
8:30-8:50 am	F. Willeke	Welcome and workshop goal
8:50-9:15 am	T. Shaftan	NSLS-II injection system
9:15-9:35 am	R. Heese	NSLS-II pulsed magnets
9:35-9:50	S. Kowalski	Septum/Bumps    Circuit    Topology    and Simulations
9:50-10:15 am	R.P. Fliller	Feasibility of NSLS-II injection scheme via pulsed sextupole magnet
10:15-11:00 am	J.-R. Chen	Pulsed magnets of the Taiwan Photon Source

11:00-11:20 am		<i>Break</i>
11:20-12:20 am	S. Mikhailov	Design and performance of fast injection- and extraction-kickers at Duke FEL/HIGS facility
12:20-1:35 pm		<i>Lunch</i>
1:35-2:20 pm	A. Ueda	Pulsed magnets for the photon factory (PF) at KEK
2:20-3:05 pm	H. Takaki	Design and field measurement of the PSM at the PF-ring
3:05-4:05 pm	H. Takaki	Results of the PSM operation at the PF-ring
4:05-5:35 pm	All attendees	Discussion on NSLS-II's pulsed magnet design
6:00 pm -		<i>Dinner</i>
Tuesday	28-July	
8:30-9:15 am	C. Burkhardt/ DeLira	A. SLAC kicker systems applicable to NSLS2 requirements
9:15-10:00 am	A. Jain	Field measurements in pulsed magnets
10:00-10:45 am	A. Wu	Looking forward
10:45-11:00 am		<i>Break</i>
11:00-12:10 pm	R. Heese	Tour of PML
12:10-1:25 pm	All attendees	<i>Lunch</i>
1:25-2:25 pm	A. Jain	Tour of RHIC
2:25-3:55 pm	All attendees	Discussion on NSLS-II pulsed magnet measurement
3:55-4:15 pm	All attendees	<i>Closing comments</i>

## Abstracts

Welcome and Workshop Goals,  
F. Willeke, NSLS-II, BNL

The goals of the Workshop are to assess the design of pulsed system at the NSLS-II and establish mitigation strategies for critical issues during development. The focus of the Workshop is on resolving questions related to the set-up of the pulsed magnet laboratory, on measuring the pulsed magnet's current waveforms and fields, and on achieving tight tolerances on the magnet's alignment and field quality.

NSLS-II injection system,  
T. Shaftan, NSLS-II, BNL

The presentation offers an overview of the NSLS-II injector and gives the specifications on the injector's parameters.

NLSL-II pulsed magnets,  
R. Heese, NLSL-II, BNL

The talk details the NLSL-II's pulsed-magnet systems, their parameters, tolerances, and designs.

Sextupole magnet,  
R.P. Fliller, NLSL-II, BNL

We investigated using pulsed multipoles to inject into the storage ring, an idea pioneered at the Photon Factory at KEK. A pulsed sextupole has the advantage that the field and gradient is zero at the center of the magnet and rises quickly off axis. We present a detailed analysis of a pulsed sextupole injection scheme for the NLSL-II storage ring. This analysis shows that the beam motion requirements on the stored beam can be met with precise alignment of the sextupole. This is weighed against difficulties in constructing the transport line. In particular, the strong position dependent gradient at the location of the injected beam makes the transport line difficult to construct and operate reliably.

Other pulsed injection schemes were also studied and are briefly discussed in this presentation.

The pulsed magnets of the Taiwan Photon Source,  
J.-R. Chen, C.-K. Chan, C.-S. Chang, H.-P. Chang, P.-J. Chou, C.-S. Fan, J.-C. Huang, C.-C. Kuo, K.-K. Lin, Y.-H. Liu, G.-Y. Hsiung, and C.-S. Yang, National Synchrotron Radiation Research Center, Hsinchu 300, Taiwan

Studies were conducted to construct the Taiwan Photon Source (TPS), a 3 GeV synchrotron-light source with an emittance of 1.7 nm-rad. Among the many important parameters, a high-performance, top-up mode injection is essential to users. This report discusses the design of the pulse magnets of the TPS. The successful results are shown of reducing the stray fields, minimizing the noise, lowering the time jitter, and improving the components' reliability. The presentation also covers experiences at the Taiwan Light Source, a recently upgraded 1.5 GeV machine with top-up injection mode.

Design and performance of fast injection- and extraction-kickers at Duke FEL/HIGS facility,  
S. Mikhailov, Duke University  
PO Box 90319, Duke University, Durham, North Carolina 27708-0319

The Duke FEL/HIGS (Free Electron Laser/High Intensity Gamma-ray Source) facility has recently undergone through a series of major upgrades. As a part of this upgrade, a kicker system was designed to provide reliable injection from the booster into the storage ring at any chosen energy in the range between 240 MeV and 1.2 GeV. The kickers had to comply with a rather challenging specification, requiring a low jitter of about 1 nS, and a pulse as short as 15 nS for extraction, and 100 nS for injection. The extraction kickers also needed a large dynamic range of the high voltage magnitude covering 4-30 kV. The kicker system was designed and fabricated by Budker Institute of Nuclear Physics, Novosibirsk, Russia. We discuss our

experience with the Duke kicker system design and operation in the prospective of their relevance for the NSLS II-kicker system.

Pulsed magnets for the photon factory (PF) at KEK,

A. Ueda, KEK, High Energy Accelerator Research Organization 1-1 Oho, Tsukuba, Ibaraki 305-0801, Japan

I'll talk about the pulse magnets for the photon factory at KEK without the pulse sextupole magnet. (Dr. H. Takaki is going to talk about the pulsed sextuple magnet into detail.) Kicker magnets: low impedance out-vacuum traveling wave type kicker magnet Septum magnets: passive septum magnet with magnetic shield And I'll mention outline of the other pulse magnets Pulse bending magnet at the Linac Kicker and septum magnets at PF Advanced Ring.

Design and field measurement of the PSM at the PF-ring and Results of the PSM operation at the PF-ring,

H.Takaki, Synchrotron Radiation Laboratory (SRL), Institute for Solid State Physics(ISSP), University of Tokyo 5-1-5 Kashiwanoha, Kashiwa, Chiba 277-8581, Japan

This talk discusses three main topics:

The stored beam stability with the PSM injection at the PF-ring; issues with pulsed magnet injection; and a case study of the possibility of PSM injection at the NSLS-II.

SLAC kicker systems applicable to NSLS2 requirements, (lower case for words as above)

C. Burkhart and A. de Lira, SLAC National Accelerator Laboratory, 2575 Sand Hill Road, Menlo Park, CA 94025

The parameters of several SLAC kicker systems are similar to those required for the NSLS2. The SPEAR3 injection kickers employ adder-type solid-state modulators, shorted strip-line kickers, and matched impedance loads. They generate 0.8  $\mu$ s, 2- to 3-kA flattop pulses with a rise and fall of less than 0.4  $\mu$ s. The damping-ring injection/extraction kickers of the SLAC linac are based on thyatron- switched PFLs that drive matched-impedance, ferrite-loaded kickers. At SLAC, these systems produce  $\sim$ 3 kA, 150 ns flattop pulses with  $\sim$ 60 ns rise/fall time. A modified version of this kicker system at KEK delivers 0.3  $\mu$ s pulses. The LCLS's BXKIK and BYKIK systems for selective beam-bunch-dumping mate an IGBT-based solid-state modulator to an inductive kicker magnet. The systems produce a sinusoidal pulse with a period of 400  $\mu$ s and up to 0.5 kA current. The design of these kicker systems, modulators and magnets, discussed.

Field measurements in pulsed magnets,

A. Jain, Superconducting Magnet Division, BNL

Field quality in accelerator magnets often is expressed in terms of harmonics that is measured very conveniently using rotating coils. However, this technique is unsuitable for fast changing fields, since the typical measurement time is several seconds. For pulsed magnets, a suitable technique must be based on the time scales of interest. For data-sampling rates in the KHz range, analog Hall probes can be employed. A non-rotating pick up coil of a suitable design will measure both the strength of the main field, and the homogeneity of the field (harmonics), over a very wide range of field strengths and time scales. Some examples are presented of recent measurements with sampling rates ranging from several tens of milliseconds to a few microseconds.

Looking forward,

W. Zhang and J. Sandberg, CAD, BNL

Repetitive-pulsed power technology is one of the fast growing areas in accelerator engineering. A trend analysis is described, and a brief review of history given. Recommendations are offered based on the NSLS II's requirements, the technology landscape, as well as our R&D, project management, and operational experiences.

## Workshop Notes

Disclaimer: These notes were taken during two discussions at the PMDM Workshop. Their intent is to informally answer the questions that the workshop focused on; they are not flow coherently, but rather represent the most important questions, answers, and comments as the discussions evolved. The Workshop participants are responsible for correcting and revising the text if they feel any changes are necessary. We welcome comments and suggestions.

Glossary: Q=question, A=answer, C=comment

Q	<b>Did anybody use glass or quartz vacuum chamber for out-of-vacuum pulsed magnet?</b>	R. Heese
A	Ceramics is the usual solution.	all
C	Duke University adopted a different solution, viz., a 10-inch diameter, 40 cm long glass with a 10- $\mu$ s pulsed magnet. This design always works well. In addition, quartz can be a solution, as it is easy to weld.	I. Pinayev
Q	What about the thermal properties of the glass material? Has anybody considered the heating the internal coating from the beam and pulsed power?	B. Sheehy
C	LCLS kicker's chambers, made from aluminum, are 1 m long with a 1 inch cross-section. However, the duration of the pulse is very slow (about 400 $\mu$ s response time).	C. Burkhart
C	The vacuum-chamber's ceramic is very expensive (30-50 k\$). What are the prices for the quartz materials?	R. Heese
A	We are waiting for pricing from the vendors.	J. Skaritka
Q	Where does NSLS-II plan to place the kicker modulators?	C. Burkhart
A	Below the kicker magnets, inside the storage-ring's injection girder.	R. Heese
Q	Are the parameters of the NSLS-II pulsed magnets fixed or are they still evolving?	Z. Wu
A	The main parameters of the magnets are defined by the injection/extraction straight-section geometry. However, optimization of the pulsed magnets and their kicker parameters is ongoing, and will continue until Final Design review in 2011.	T. Shaftan
Q	<b>What is the experience using SCRs on pulse-to-pulse timing jitter?</b>	G. Ganetis
A	The minimum achieved jitter is about 0.5ns for pulsed-magnet systems. This is possible with the Thyrotron systems, but difficult with the SCR-based systems.	S. Mikhailov

Q	What is the experience with short-pulse kickers at the Taiwan Photon Source? Why they chose to develop in-vacuum rather than out-of-vacuum extraction kickers for their booster?	T. Shaftan
A	We found that using a modulator-driving voltage higher than 25 kV results in poor reliability of the system. Thus, we designed kicker magnets with smallest possible aperture so to minimize the required voltage.	J.R. Chen
Q	<b>Have you considered other ceramics for the vacuum-chamber material?</b>	B. Sheehy
A	A Japanese company manufactured our ceramic chambers. We are investigating opportunities for producing and coating the ceramic chambers at other companies.	J.R. Chen
C	Comment: 25 kV is indeed the limiting voltage beyond which we might expect a dramatic reduction in the reliability of the pulsed system.	S. Mikhailov
C	Comment: To reduce stray fields from a pulsed magnet, a 0.35 mm silicon steel covers the KEK's 2mm septum copper coil. This has reduced the stray field, which was at the level of 350 Gs, to below 10 Gs. The high magnetic permeability of the silicon-steel helps in shielding the septum field.	A. Ueda
Q	Question to A. Ueda: Did you try high-pressure epoxy impregnation? Can this method help to prevent voids in the epoxy?	S. Mikhailov
A	That method would help. However, KEK did not use pressure impregnation for kicker high-voltage cells.	
Q	Question to H. Takaki: How was the location of PSM chosen in the lattice? In passing the PSM, does the injected beam see a different tune relative to the stored beam?	I. Pinayev
A	This consideration was taken into account during testing the PSM arrangement via one-turn tracking, which gave exact phase advance.	
C	Comment: The PSM experiment demonstrated that the injection rate with PSM is equal to approximately half of the rate with a conventional four-kicker bump.	H. Takaki
C	Comment: Also: The requirement of having a high rate of PSM injection severely restricts the choice of suitable betatron tunes for the PF ring.	
Q	Which bunch pattern was used for the PSM experiments, a single bunch or a train of bunches?	T. Shaftan
A	A single bunch was used.	H. Takaki
Q	What is the actual accuracy of measurement of PSM field?	T. Shaftan
Q	What is the accuracy of determining the PSM axis?	

A	The mechanical accuracy of the alignment fiducial on the PSM is better than 50 $\mu\text{m}$ . The actual accuracy of measurements of the PSM field apparently is difficult to estimate.	H. Takaki
Q	<b>What are consequences of driving all four kickers in parallel using a single, high-current power supply?</b>	R. Heese
Q	In particular, how can you compensate for realistic differences between the kickers in terms of waveforms and timing?	B. Parker
A	One way to equalize the kicker fields is to shunt the others, rather than the weakest kicker. The shunting procedure should be transparent so the shunts can be retuned whenever this is required.	R. Heese
C	Comment: Duke University employs a composite kicker magnet with two coils. . Field oscillations between them make matching difficult.	I. Pinayev
C	The issue here is how to develop identical magnets, together with identical vacuum chambers. The complete four-kicker system can be characterized via beam-based measurement.	S. Mikhailov
Q	<b>Requirements for such a power supply driving all four kickers are 24 kA, 4 kA/<math>\mu\text{s}</math>, 3.6 kV half-sine. What are the potential issues with such supplies?</b>	T. Shaftan
A	A high current rate is needed. However, there exist IGCT devices that can generate 10kA/ $\mu\text{s}$ and these devices can operate at 6.5 kV. The high-voltage switch will see double voltage, but then an IGCT could be used (ABB will sell a stack of voltage).	C. Burkhart
A	Differences in kickers are adjustable by correcting the inductive loads on every magnet. However, this method has limited Not adjustable.	R. Heese
C	Comment: What was missing in the scheme presented in Steve Kowalski's talk are the parasitic losses; these losses make kicker systems different from device to device.	C. Burkhart
C	Comment: However, if the kickers + drivers can be made identical, using the same technology the losses can be made nearly identical for different devices.	S. Mikhailov
C	Comment: Driving all SCRs with a single pulser does not seem to be a good idea because of the potential mismatch.	B. Sheehy
A	Comment: Actually, this design is feasible if all kind of waveforms and field corrections are built into the pulsed-system's design.	S. Mikhailov
A	Comment: You can minimize differences between different devices by fully optimizing the device's parameters; a) using field- and current-measurements, and, b) characterizing the device's performance using beam-based methods.	T. Shaftan

Q	<b>How accurately can storage-ring kickers be aligned?</b>	T. Shaftan
A	One way of correcting an undesirable horizontal field lies in using the skew dipole scheme of Bx correction.	R. Heese
C	Comment: The disadvantage of that scheme is the need of continuously monitoring the kickers' alignment.	I. Pinayev
C	Comment: There are limitations on the accuracy of alignment. There can be a 10 um discrepancy or worse in alignment between the survey on the measurement bench and then rechecking magnet survey in the tunnel.	S. Mikhailov
C	Comment: The measurement coils can be calibrated to increase accuracy of the alignment in the following way: Start with DC measurements, then make AC measurement with a sinusoidal current, and lastly measure the actual pulse to calibrate the coils.	S. Mikhailov
C	The last stage of the alignment is a final alignment with the electron beam.	S. Mikhailov
Q	What are the magnet errors achieved at the TPS?	T. Shaftan
A	TPS achieved about 1% of differences in the field amplitude; every kicker sits on its own positioning stage. The alignment accuracy then is limited to few $\mu\text{m}$ across of 30 cm. Accelerator physicists set the specifications for acceptable kicker errors; nobody discussed these tolerances with the TPS users.	J.R. Chen
Q	How can you bleed the current off to feed the correction coils in a kicker?	C. Burkhart
A	We considered making slim correction coils (single turn) fed consecutively for the same power supply through a shunt so to adjust the amount of current flowing through the correction coil.	R. Heese
Q	How do you keep current in phase with the main pulse using correction coils?	C. Burkhart
A	If this appears to be a problem, we can consider using separate drivers for correction coils driven by a half-sine waveform.	R. Heese
Q	<b>Let us discuss the booster extraction kicker that requires 0.2% of the waveform flatness along the 300 ns-long portion of the kicker pulse (200 ns rise time, 300 ns flattop) so not to spoil the extracted beam's emittance.</b>	T. Shaftan
C	Adjusting the driver's impedance might compensate for the droop.	I. Pinayev
C	The CERN kicker assures 1% of the flattop's flatness.	Z. Wu
C	I believe that a 1% value is achievable.	P. Zuhosky
C	I concur that 1% is achievable; however, we did not specify this tolerance for the TPS machine.	J.R. Chen
C	Less than 1% is very difficult since it may take a lot of stages in the kicker's modulator.	S. Mikhailov

C	The NLC's kickers had 60 cells generating pulses 2-3 $\mu$ s long.	C. Burkhart
C	The kicker-to-load distance is equivalent to the second pulse being $\sim$ 100ns away. Therefore, a load mismatch will affect the pulse later.	C. Burkhart
C	The measured DCCT signal does not represent correctly the actual field waveform seen by the beam. Filtering out modulation through the kicker ferrite and the coating limits the bandwidth.	S. Mikhailov
Q	<b>If we assume that the modulator violates the specification, can we consider some kind of a correction circuit to correct the waveform modulation and slew?</b>	T. Shaftan
C	As we discussed, a separate correction magnet might be installed later in the beamline.	R. Heese
C	Rather than the magnet, which will require a ceramic break, a correction stripline might be developed with $Z=50$ Ohm and high-power electronics for generating a programmable waveform.	T. Shaftan
C	This problem also can be solved by two extraction kickers with the same waveforms shifted by 1/2 period of modulation. Then, the second kicker's waveform will cancel the modulation of the bunch-to-bunch angle induced by the first kicker's nonuniform waveform.	J.R. Chen
C	A similar technique was used in the instrumentation of the NSLS's EPW (Elliptical Polarized Wiggler).	G. Rakowsky
C	In searching for a flat waveform, PFL might be used rather than PFN. It will take shaping a water line for 2 kA and 20 kV (10 Ohm impedance); for example, 150 ns is equivalent to 11 feet of water line. The challenge is using PFL is that it is not a constant impedance, but this can be improved by changing the geometry of the PFL's inner conductor to match the required value of the impedance. On other hand, aging of the PF can be a problem for the long-term operations.	C. Burkhart
C	A reduction in PS voltage is highly rewarding; to do so requires minimizing the magnet's aperture and, in turn, going to the in-vacuum magnet design. Advantageously, the in-vacuum fast kicker design is simple and perhaps less expensive than other designs. However, ferrite might be damaged by synchrotron radiation; hence, this needs to be checked.	J.R. Chen
	The voltage specifications are 12 kV for 100 ns rise time for the booster injection and extraction kickers. The charge voltage on the line is twice that of the required voltage on the magnet = 12 kV x 2= 24 kV. There are 70 kV/2 kA thyrotrons, which are discussed on the E2V's website. An issue is the required current rate, viz., $di/dt=20A/ns$ , which will be hard to meet. A two-gap thyrotron may be a good resolution for 10 kA/ $\mu$ s. We recommend calling E2V and asking if they have anything with 20 kA/ns.	C. Burkhart

C	Some other recommendations are exploring solid-state options. Adder is a good solution.	C. Burkhart
Q	<b>For the injection into the booster we are considering the four-kicker scheme that has not been used before in this context. What issues do you see with this scheme? We are planning on feeding two neighboring kickers with the same power supply because there are difficulties in controlling two pulses independently.</b>	T. Shaftan
C	The NSLS-II linac will generate high-charge beams with the longitudinal phase-space dominated by the energy droop along the bunch train. This may affect beam stacking using the four kickers.	I. Pinayev
C	A 50 kV thyrotron exists that can be used in the pulser simultaneously for both kickers. Its use requires prior analyses.	C. Burkhart
C	These will be relatively low-field devices, wherein magnet hysteresis may play a role in the mismatch between different kickers.	C. Burkhart
C	Hysteresis is very small at 500 Gs.	S. Mikhailov
C	The ferrite material CMD5005 is of the highest quality and has the smallest hysteresis.	R. Heese
C	Cable losses must be taken into account that may be quite significant for long lengths. For example, 100 feet of cable used in kicker system BYKIK (SLAC) result in large losses in the cable, equivalent to about 0.5 Ohm.	C. Burkhart
C	IGBTs may be of interest to use in such devices. Upeck (Mitsubishi) manufactures them.	C. Burkhart
C	Glazman, Lambda (ILE) produces IGBTs operating at 3.3 kV; even 6.5 kV versions of them exist.	A. DeLira
C	We use two-stage modulator with IGBT on first stage and Thyatron on the second stage, which may be useful. In the analysis of such a scheme, it may be important to explore the prepulse, relevant to energy transfer from the 1st to 2nd stage.	C. Burkhart
Q	<b>Two or four kickers in parallel may cause reflections between the different devices.</b>	A. De Lira
A	This can be carefully modeled in circuit analysis to see the importance of the effect.	G. Ganetis
A	AC measurements of the coupling between the magnets can help in minimizing the coupling.	S. Mikhailov
C	A back-up plan is needed for four separate modulators for the storage-ring kickers.	G. Ganetis

Q	<b>Let us discuss methods of the online measurement of kicker fields.</b>	T. Shaftan
C	The measurement circuit at Duke University uses 8 coils with BNC connectors on the ends. By subtracting the readings, this scheme allows us to deduce the aging of the pulsed-magnet ferrites.	S. Mikhailov
C	Today's Hall probes can measure magnetic fields in the MHz or even 10s MHz range. At these high frequencies, we must be careful with twisting the coils and creating other problems that might limit the bandwidth.	S. Mikhailov
C	Impedances in GOhm range define the time-constant of a measurement circuit. Therefore, the measurement circuitry must be analyzed carefully for any particular case.	A. Jain
C	There are several manufactures of fast transformers: Pierson from Palo-Alto Cal, Bergoz in GHz range. Stangenes also has them with a 2 ns bandwidth limit. To match the measurement device bandwidth we should buy 1 GHz and a 10-bit digitizer.	G. Ganetis
C	To characterize the high-frequency modulation of the kicker waveform we could try offsetting the transformer pulse.	B. Sheehy
C	Another way to do this is to subtract the averaged (HF filterer) pulse from the measured pulse.	T. Shaftan
C	Aquarius sells a 3 GHz 10-bit digitizer.	B. Sheehy
Q	A problem with the Pulsed Sextupole Magnet lies in measuring the zero-field point at the maximum current.	H. Takaki
A	We considered building a differential coil with symmetric loop geometry to subtract fluxes from the two opposite halves of the magnet.	R. Heese
A	We at KEK are using a measurement system consisting of a coil and a filter.	H. Takaki
C	Commenting on storage-ring kickers that require very high precision on alignment and field quality, we note that the kicker field will change pulse-to-pulse as determined by hysteresis in ferrite. Hence, the actual BH curve must be taken into account while estimating the achievable tolerances for the kicker-magnet's design.	S. Mikhailov
C	Another comment is that defining the multipole magnetic center itself is quite unclear when the range of interest is only tens of microns. Thus, the center of the pulsed sextupole magnet may be determined only with limited accuracy (potentially limited to $\mu\text{m}$ or so).	T. Shaftan, S. Mikhailov
Q	<b>How can we measure fields with accuracies of 0.1% of waveform in amplitude and time?</b>	G. Ganetis
C	We might employ a differential way by comparing the measurements between different kickers. Another differential method is to use two zero-flux transformers.	S. Mikhailov

C	DCCT's and Pierson's white band current transducers reach a measurement reproducibility of 1E-4 peak-to-peak.	G. Ganetis
C	A problem here might be shot-to-shot stability of the kicker waveforms at this level.	P. Zuhosky
C	A laminate construction might be used rather than ferrite. The permeability of this kind of material is much higher, thereby resulting in better magnetic properties. Hitachi produces a material called Finemet, including 3 different major classes of these materials with different anneals.	C. Burkhart
C	These magnetic materials were discussed by Hitachi at the PAC-2009 conference. We are considering to electrically discharge machine (EDM) the actual kicker's shape or cut it with a laser.	R. Heese
Q	<b>Temperature compensation of the pulsed magnets must be considered to achieve such high levels of the measurement accuracy. Also, aging of the magnets may necessitate online adjustment of power supplies.</b>	G. Ganetis
C	The kicker magnet's alignment can be lost within 5 min of operating at the 10 urad level.	I. Pinayev
C	The tunnel temperature is well maintained, within 0.1 degree. This will stabilize the performance of the magnet and driver.	G. Ganetis
C	The NSRRC achieves temperature stability within 0.1 deg.	J.R. Chen
Q	<b>What are your thoughts on measuring the parameters of thyrotrons?</b>	G. Ganetis
C	A bench procedure for assessing jitters in the switching devices should be developed before formulating the kicker drivers. For example, IGBTs exhibit a 2-ns jitter.	C. Burkhart
C	One way to resolve problems with the high dIdt in thyrotrons is to use a small magnetic switch in parallel with thyrotron ("saturable reactor") working whilst the thyrotron turns on.	C. Burkhart

**NSLS-II pulsed magnet parameters as of July 2009**

Pulsed Magnet/Parameter	Numbers required	Bend Angle (mR)	Length (m)	Max. Field (T)	Bend Radius (m)
Ring Injection Kicker (bump)	4	7.85	0.5	0.157	63.678
Ring Injection Septum	1	40	0.8	0.5	20
Ring Injection Septum DC	1	150	1.8	0.833	12
Pulsed Sextupole	1	2.83	0.5	0.055 @ 8.5mm	
Booster Extraction Slow Bump	4	7.5	0.2	0.375	26.667
Booster Extraction Kicker	1	5	1	0.05	200
Booster Extraction Septum	1	48	0.6	0.8	12.5
Booster Extraction Septum - DC	1	96	1	1.009	10.417

# Pulsed Magnet Design and Measurement Workshop

Brookhaven National Laboratory, July 27-28, 2009

## Workshop Goals

F. Willeke, NSLS-II AS Division Head

## Introduction

NSLS-II Main Design Features and Requirements:

- 3GeV Beam Energy
- Small emittance  $<1\text{nm}$ , 10% relative stability
- Large beam current,
- Touschek limited lifetime,
- Frequent (top-off) Injection

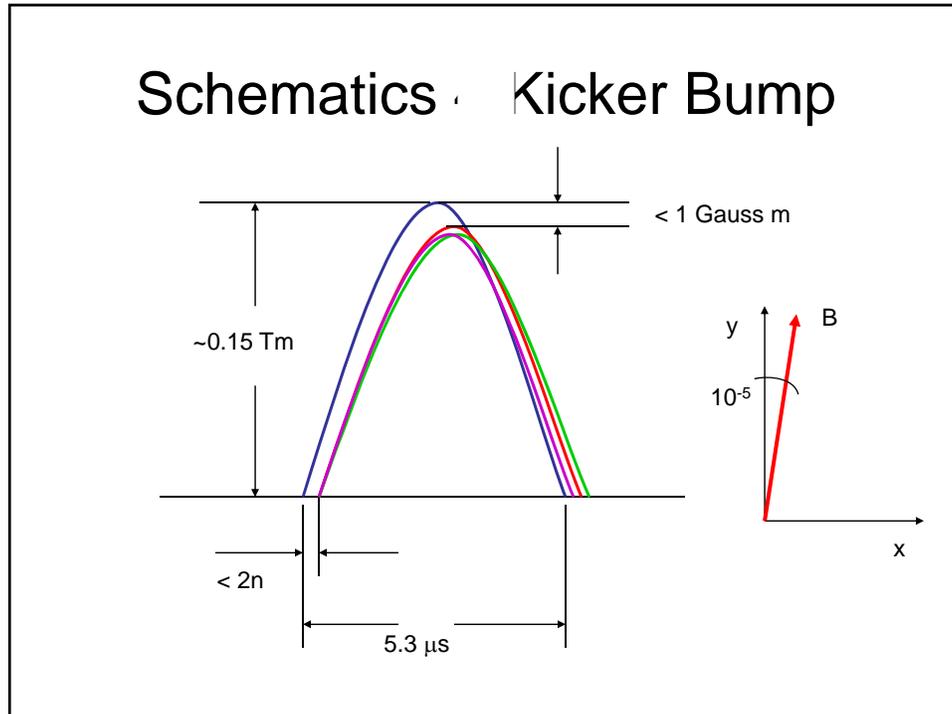

➔ **Requirement on Injection System**

## Present Status and Time Line

- Building construction in Progress
- Procurement of major components (linac, booster, magnets, vacuum chambers in progress)
- Production of components in 2010-2011
- Installation 2011-2012
- Testing and commissioning 2013-2014

## Requirement on Injection System

- Injected beam oscillates within a 10mm aperture (measured in centre of long straight)
- Stored beam should not oscillate more than 10% of its size  
 $\sigma_x \sim 100\mu\text{m}$ ,  $\sigma_y \sim 5\mu\text{m}$
- Rel Kicker Amplitude Precision (kicker-to kicker over entire pulse referring to peak)  
 $10^{-3}$  horizontal (over pulse referring to peak)
- Field Angle  
 $5 \cdot 10^{-5}$  vertical (field angle)
- Timing precision and stability  $< 2\text{ns}$   
(kicker-to-kicker)

## Workshop Goals

- Discussion of alternative injection schemes, dipole kickers, nonlinear kickers, DC Bump ....
- Pulsers: Discussion of Switching Technology
- Pulse Shaping Methods: PFN, Cable Discharge, others
- Quest of Pulsed Correction Circuits
- How to achieve identical pulse shapes and amplitudes?
- How to measure and verify  
Biggest Challenge: Field Direction ( $\sim 1\text{E-}5$ )

## Injector Overview

T. Shaftan  
Injector group leader

Pulsed Magnets Design and Measurement Workshop  
July 27-28, 2009

1

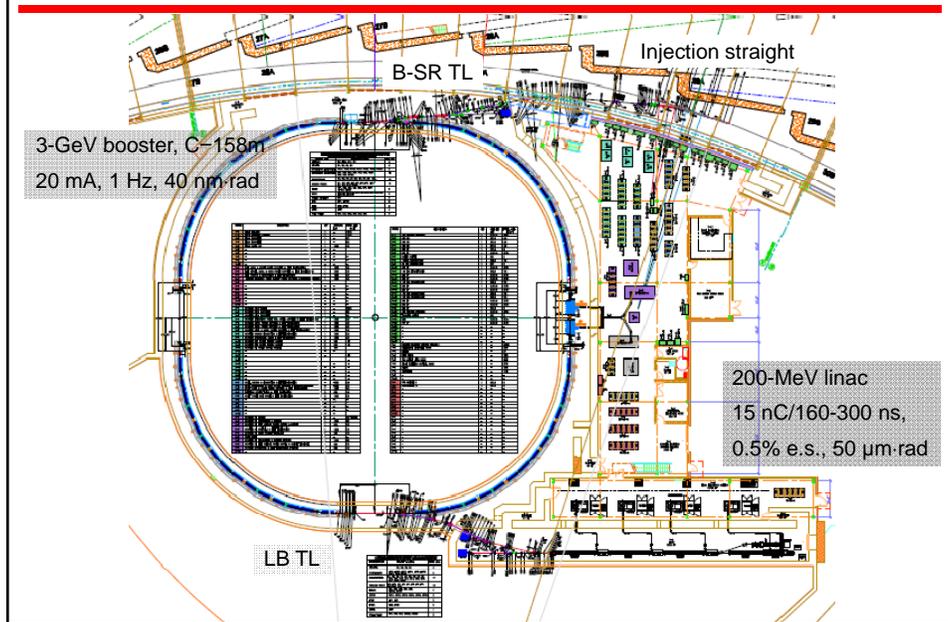

## Scope Overview

- NSLS-II requires a reliable injector capable of filling and maintaining storage ring current. Top-off mode of injection is required
- Specifications for NSLS-II injector
  - Storage ring: 3 GeV, 0.5 A, 1080 bunches in 1320 RF buckets, 3 hr lifetime
  - Top-off: deliver 80...150 bunches with 7.3 nC total charge once a minute → total stability of ring current 0.55%, bunch-to-bunch charge deviation 20%
  - Repetition rate of 1 Hz (initial fill 0 → 0.5 A in 3 min)
- Supported Storage Ring Bunch patterns:
  - Baseline: uniform fill with 20% ion-clearing gap
  - Baseline: 4-5 bunch trains with short gaps
  - Future upgrade: camshaft bunch(es), uniform fill
  - Future upgrade: Bunch cleaning, Empty/Full RF bucket charge ratio 0.01%
- Injector scope:
  - 200-MeV linac with 100-keV thermionic gun
  - Linac-to-booster transport line
  - 3-GeV booster
  - Booster-to-Storage ring transport line
  - Storage ring injection straight section

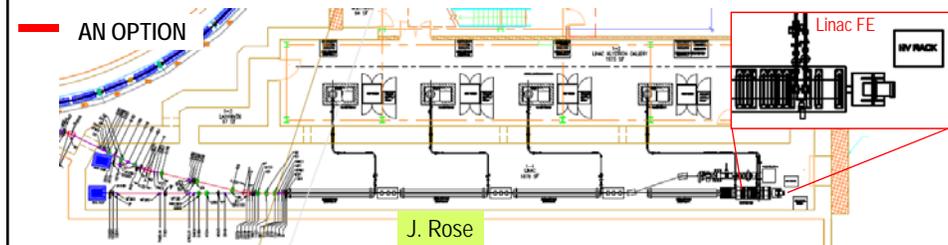

2

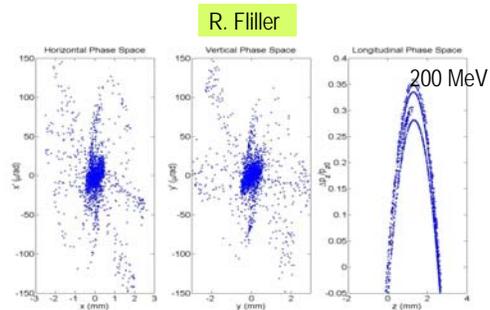

# NSLS-II injection system

## Linac

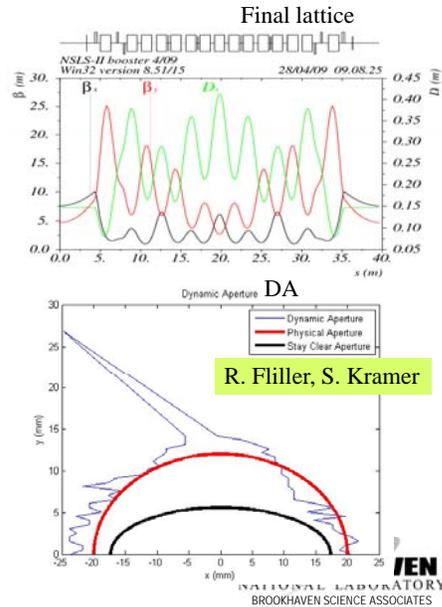

- Procurement is under way
- Design and Modeling
  - Linac model is developed
  - Linac beam dynamics study completed
  - Linac Front-End diagnostics station design is assessed
  - Set-points and tolerances
  - Initial conditions for transport line
  - Diagnostics performance

## Booster

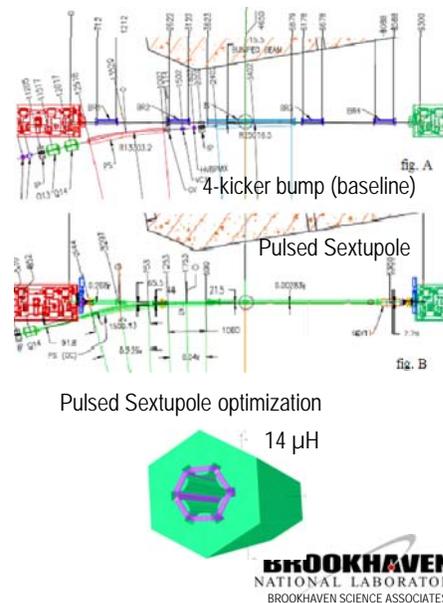

- Design is completed
  - Final lattice has been developed
  - Lattice is tested with realistic errors (150 $\mu$ m misalignments, 0.2 mrad rolls, 0.02% in B, 0.5% in Q)
  - Orbit correction scheme is efficient
  - Conclusion: booster lattice is robust and has sufficient DA for injection
  - Turn-key procurement
- Injection
    - Septum
    - 4-kicker bump
    - Beam stacking
  - Extraction
    - Septum
    - Slow 4-magnet bump
    - Kicker

5

## Storage ring injection straight section

- Pulsed magnet tolerances were estimated
- To keep the disturbance of the electron beam below 0.1 of the beam size:
  - 1E-4 in relative kicker amplitude mismatch
  - 12  $\mu$ rad in the tilt angle of the kicker magnet.
- Other LS run with much weaker tolerances
- Feasibility studies of "quiet" magnets to begin once PML is available
- Alternative idea of injection via Pulsed Sextupole (PSM, as in KEK) have been studied as an option
  - Injection straight section layout is altered to accommodate new scheme
  - Magnet parameters are calculated: magnetic design is completed
- Search for advanced PSM schemes
  - Reduce magnet inductance (and  $V_{PS}$ )
  - Reduce focusing of injected beam

6

## Transport lines

- List of TL components below
- Diagnostics TLs will be used for linac and booster commissioning

TL equipment	LTB	BSR
Dipole	4	4
Quad	17	16
Corrector	10	17
Dipole PS	1+1	4
Quad PS	12+6	12+4
Corrector PS	9x2	9x2
ICT	2	2
FCT	2	2
BPM	6	7
Flag	9	9
Energy slit	1	1
Pumps	10	11
Gauges	3	4
Valves	5	6
Dipole chambers	2	3
Chamber to dump - Y	2	1
Quadrupole pipes	8	7
BPM block machining	8	7
Drift pipes	18	27

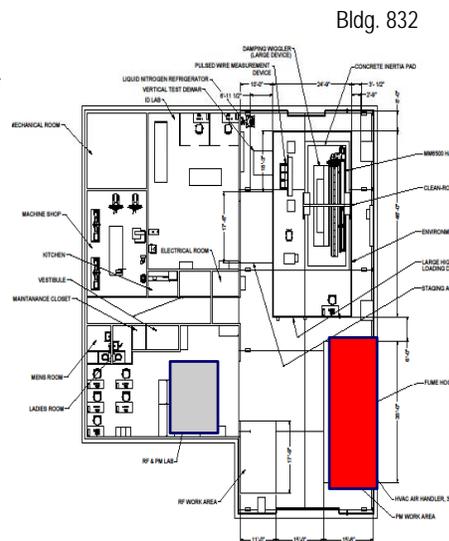

7

## Pulsed Magnet Lab Status

- Pulsed Magnet lab is being set up for
  - performance evaluation and calibration of final magnets
  - test innovations and concepts required to make top-off operation transparent to NSLS-II users
- Tolerances required to have non-invasive top-off injection will be difficult to meet and maintain, some innovation is required
- PML status
  - Lab space assigned, materials/tools on order
  - 35 ft. x 15 ft. caged, interlocked test area under construction
  - Sr. Scientist, Experienced Head Technician, post-doc, EE, consultants are on board full time
  - First order of business: Pulsed sextupole prototype construction and evaluation

## Injector schedule

---

- Prior to CD-3 injector schedule was motivated by funding limitations
- Current situation is favorable for expediting the injector schedule to:
  - Meet advanced building schedule
  - Procure major injector subsystems earlier
- Injector building BOD – 18 May 2011
- Linac turn-key procurement award – Nov 2009
- Booster RFP solicitation begins – Oct 2009
- Schedule of utility distribution will match the linac and booster delivery schedule
- Development of Diagnostics TLs to be advanced for early linac/booster commissioning
- Injection straight section is tied to the SR schedule
- Complete Pulsed Magnet lab soon for building prototypes of challenging pulsed magnets

9

2

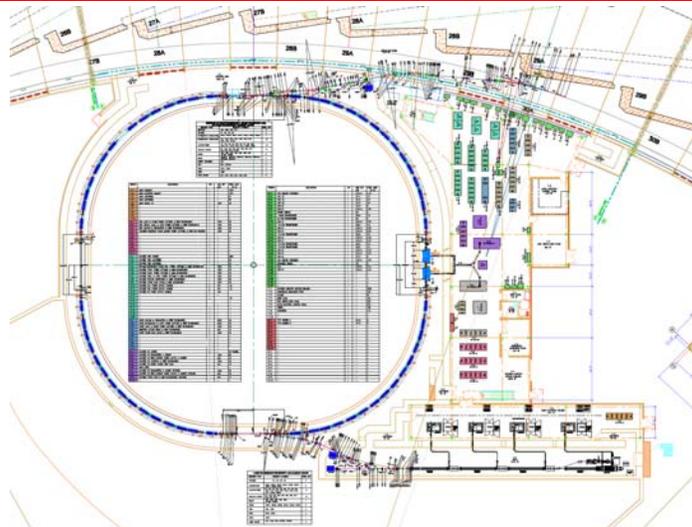

## Outline

---

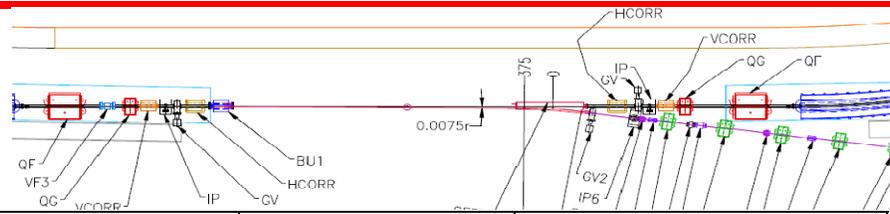

- Booster Injection, single pulse train or more
- Booster extraction, stability criteria for two types of ring injection
- Storage ring injection, top-off user requests, kicker stability and alignment requirements
- Pulsed sextupole or four kickers?
- Pulsed magnet lab

## NSLS-II Injection Complex

---

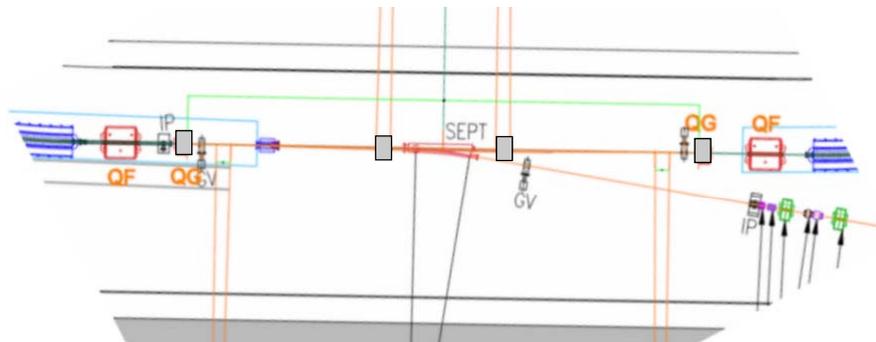

## Baseline Booster Injection

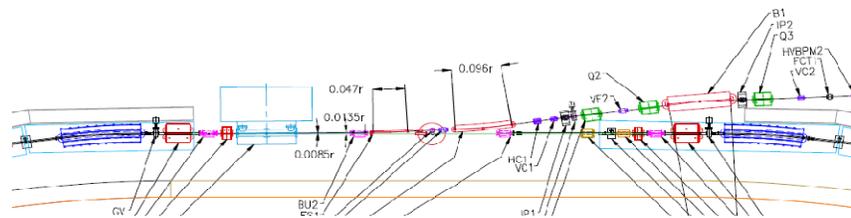

Parameter	Pulsed septum	Kicker
Length, m	0.75	0.2
Field, T	0.127	0.025
Angle, mrad	142.5	7.5
Aperture x/y, mm	20/15	67/27
Pulse shape, $\hat{I}$ , $\hat{E}$	Full sine 100 $\mu$ sec 1800A, 200V	300 nsec flat-top, <100 nsec rise/fall time, 800A, 7800V
Field Error tolerance, %	<1	~1
Align.tol., roll (mrad)	100/100/0.2	100/100 /0.2

## Booster injection with 4 bumps

- To reduce demand for linac charge – two pulse train transverse stacking injection, 0.1 to 0.2 seconds apart may be an alternative injection scheme
- Bump parameters: Same as injection kicker, but 0.05T, 100 nsec rise and fall time with 300 nsec flat-top

## Baseline Booster Extraction

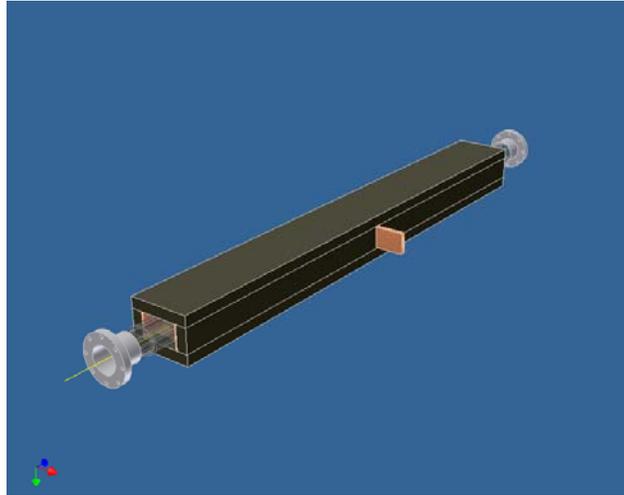

Parameter	Orbit Bump	Extraction Kicker	Pulsed Septum	DC Septum
Length, m	0.2	1	0.6	1
Field, T	0.375	0.05	0.8	0.96
Angle, mrad	7.5	5	48	96
Aperture x/y, mm	70/27	70/44	32/23	50/20
Pulse shape/width (Flat-top), $\hat{I}$ , $\hat{E}$	$\frac{1}{2}$ sine 1000 $\mu$ s, 440A, 365V	200nsec risetime (300ns), 1926A, 31kV	$\frac{1}{2}$ sine 50 $\mu$ s, 16100A, 1062V	n/a
Flatness/ Field Error tolerance, %	n/a/0.5	<b>0.2 ripple &amp; droop</b>	<b>0.02</b>	n/a/0.01

## Extraction Kicker Parameters

Bending Angle:	5.0 mR for 3 GeV
Magnetic Field:	0.05 T
Magnet length:	1 m
Full magnet vertical gap:	0.042 m
Full magnet horizontal gap:	0.07 m
Type of magnet:	Window frame
Required current:	1900 A in 1 turn
Current pulse shape:	100 nsec rise time, 300 nsec flat-top, fall time not critical
Ripple and droop of current pulse:	<0.2 %
Repetition rate	1 Hz
Magnet Inductance:	1.737 $\mu$ H
Magnet resistance:	10 – 12 m $\Omega$ @ 2.5 MHz
Magnet Impedance (calculated):	1.6 m $\Omega$

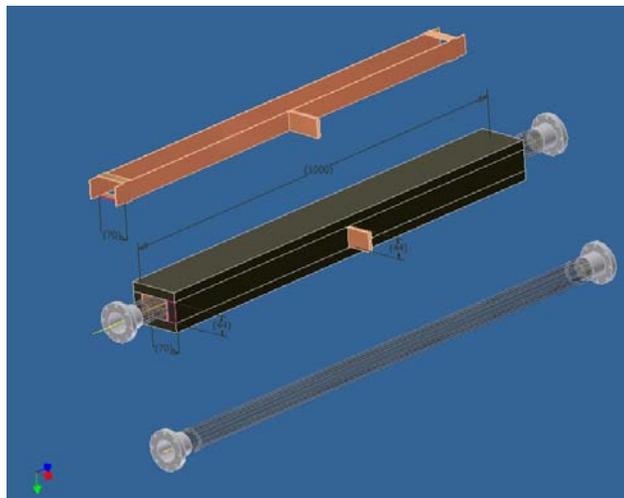

## BEK Assembled

---

## BEK Exploded

---

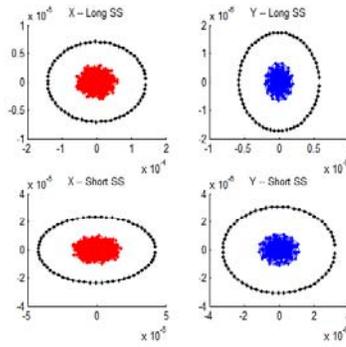

# Tolerances for Storage Ring Top-off Injection

- Transparent top-off cycle is highly desirable
- Orbit motion of 10% of rms beam size of damped beam in synchrotron is a challenging requirement for top-off

For the two alternative injection schemes, four kickers or pulsed sextupole magnet, the following parameters are required due to the very small ring emittance:

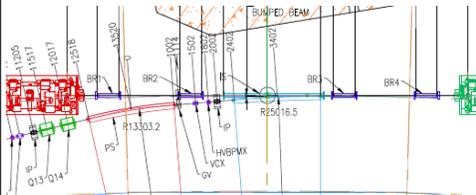

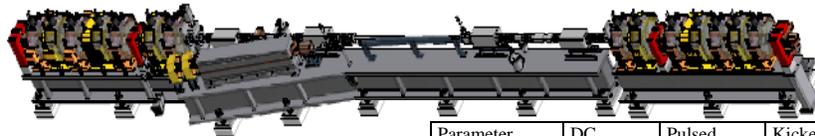

- Relative field tolerance among the injection bumps of <0.008%
- Vertical alignment of injection bump roll to better than 12.5  $\mu$ rad
- For alternative PSM injection, vertical placement of magnet to <10  $\mu$ m
- **Many modern Light Sources run successfully with more moderate tolerances**

Phase space in ring straight sections

# Baseline Ring Injection Straight Section

- Four Kickers
- Pulsed Injection Septum Magnet
- Thick Injection Septum replaced by DC magnet

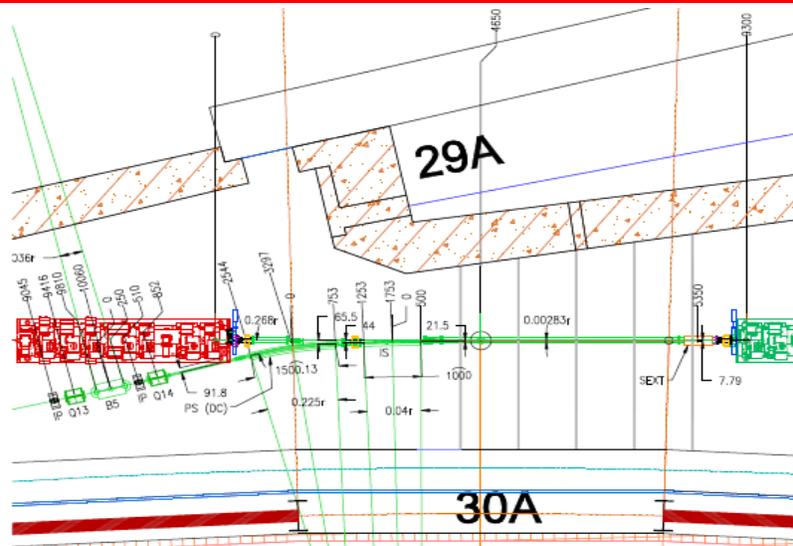

Parameter	DC septum	Pulsed septum	Kicker
Length, m	1.8	0.8	0.5
Field, T	1.056	0.5	0.157
Angle, mrad	190	40	7.85
Aperture x/y, mm	50/20	32/23	70/44
Pulse shape/width, $\mu$ s	n/a	Full sine, 100	$\frac{1}{2}$ sine 5.2
Flatness/ Field Error tol. %	n/a/0.03	0.2/0.2	8x10E-3
Align. tol. $\mu$ m/ $\mu$ m/mrad	100/100/0.2	100/100/0.2	100/100,0.012
Inductance, $\mu$ H	n/a	1.399	1.009
$\hat{I}$ , kA/ $\hat{E}$ , kV		11.9/0.885	6.05/3.594

## Approaches to Precision Matched Orbit Bumps

- Careful construction of bump drivers and connections
- High resolution voltage regulation charging supplies
- Precise magnetic measurements and careful trimming of capacitances and inductances
- Installation of  $H_t$  windings in bump magnets to compensate for roll errors
- Precision measurement of pulse currents and possible feed-forward
- Beam-based alignment of individual bumps
- Sturdy construction to alleviate mechanical vibration effects
- Possible magnet placement on externally controlled micro-positioning supports

## Pulsed Sextupole Injection Straight

## 4-Kicker – PSM Comparison

I(kA)/V(kV)	n/a	10.07/0.885	3.2/27

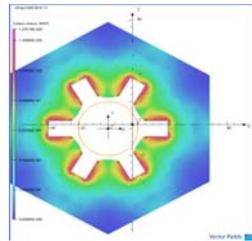

### Aspects

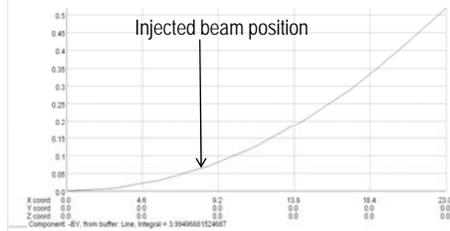

- 2 pulsed magnets only
- Transport line so far not satisfactory due to large gradient of sextupole at end of transport line
- Magnet made of thin 0.2 mm laminations, final pole contour EDM cut after assembly
- Micro-positioning table for vertical adjustment designed

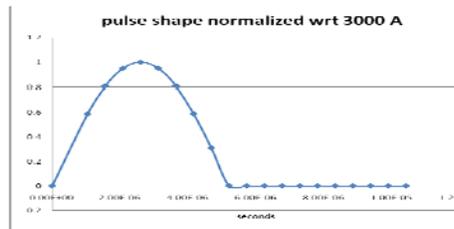

## Pulsed Sextupole Characteristics

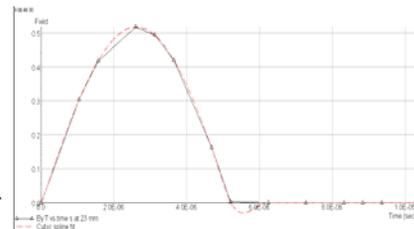

Magnetic field in magnet body

By of pulsed sextupole

Current pulse used for calculation

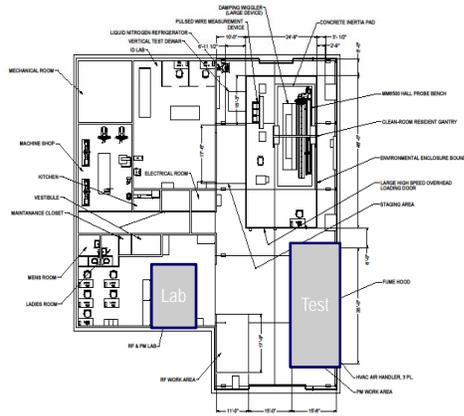

Resultant pole-tip field of pulsed sextupole

## Pulsed Magnet Lab

- Pulsed magnet lab is being set up, not only for performance evaluation and calibration of final magnets, but to test innovations and concepts required to make top-off operation transparent to NSLS-II users.
- The tolerances required to have non-invasive top-off injection will be difficult to meet and maintain, innovation is required

## Pulsed Magnet Lab Status

- Lab space assigned, materials/tools on order
- 35 ft. x 15 ft. caged, interlocked test area under construction
- Scientist on board full time
- Experienced Head Technician hired
- Post-Doc on board since April
- Engineer hired and beginning work
- First order of business: Booster extraction kicker and pulsed sextupole prototypes construction and evaluation

Plan view of Bldg. 832 – Lab area and test area highlighted

## Pulsed Magnet Test Area (5/29/09)

## Pulsed Magnet Test Area

## Injection System Value Engineering Activities

- Booster injection septum moved to upstream end of injection straight to adapt to more capable transport line and reduction of field requirement of injection kicker magnet\*

### Further investigations

- Ring injection with pulsed sextupole magnet
- Double Lambertson septum PSM for ring injection
- Can septum magnets be built similar to NSLS septum magnets
- Four bump injection into booster as back-up for reduced linac charge\*\*

\*The simple single bump booster injection scheme has been de-emphasized for now because...

\*\*The four bump booster injection scheme is being pursued to guard against reduced charge output from linac by injecting 2 consecutive linac pulses spaced by no less than 100 milliseconds (transverse stacking) before accelerating.

## Looking Ahead

---

- Completion of pulsed magnet lab set-up
- Construction of prototype booster extraction kicker, pulsed sextupole, and their drivers
- Finalizing ring injection scheme
- Decision on in-house construction or procurement of pulsed magnets
- Pulsed magnet workshop 27, 28<sup>th</sup> July

## Summary and Conclusions

---

- Injection magnets and parameters are well understood and require engineering solutions
- Due to small emittance of storage ring (especially vertical), top-off injection without disturbing the users is a challenge for the ring injection system
- Pulsed sextupole injection shows promise but presents other complexities for the transport line
- Stability of extraction out of the booster is part of this challenge
- Back-up booster injection is viable
- Pulsed magnet lab is a necessity to resolve these issues and find solutions

## Extra Stuff

---

- NSLS Septum - 4 slides
- Half/full sine wave model - 2 slides
- NSLS laminated septum 1.1T @ 16,100 A
- Flat-top driver

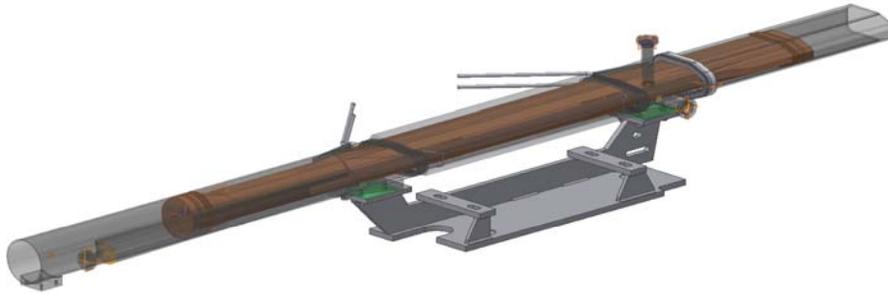

## NSLS Type Septum Magnets

---

- Main advantage is that there are no feed-throughs for high current pulsed power into vacuum
- Sturdy, simple construction with very little perturbation in beam chamber as seen by circulating electrons
- Experience with these magnets very positive – they can, however, be improved as far as fringing fields

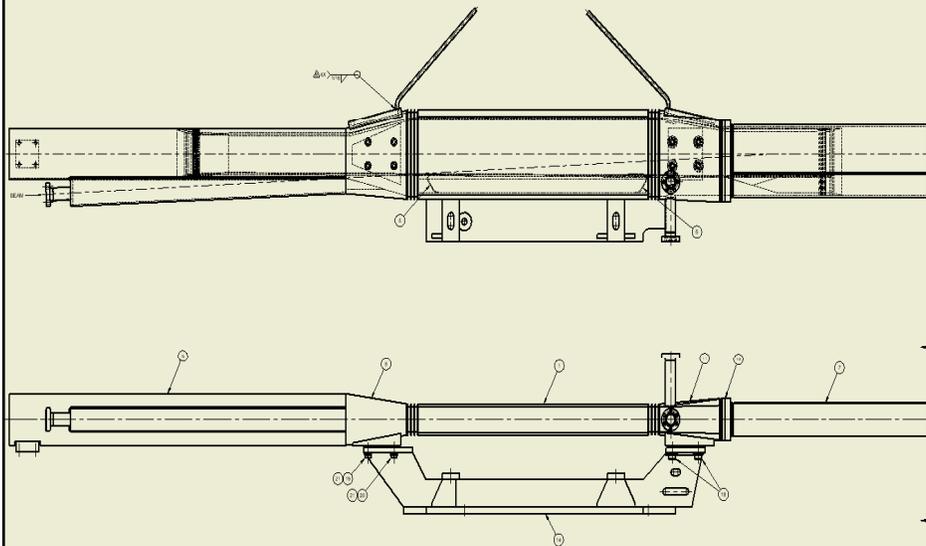

## NSLS Injection Septum, Transparent Beam Pipe

---

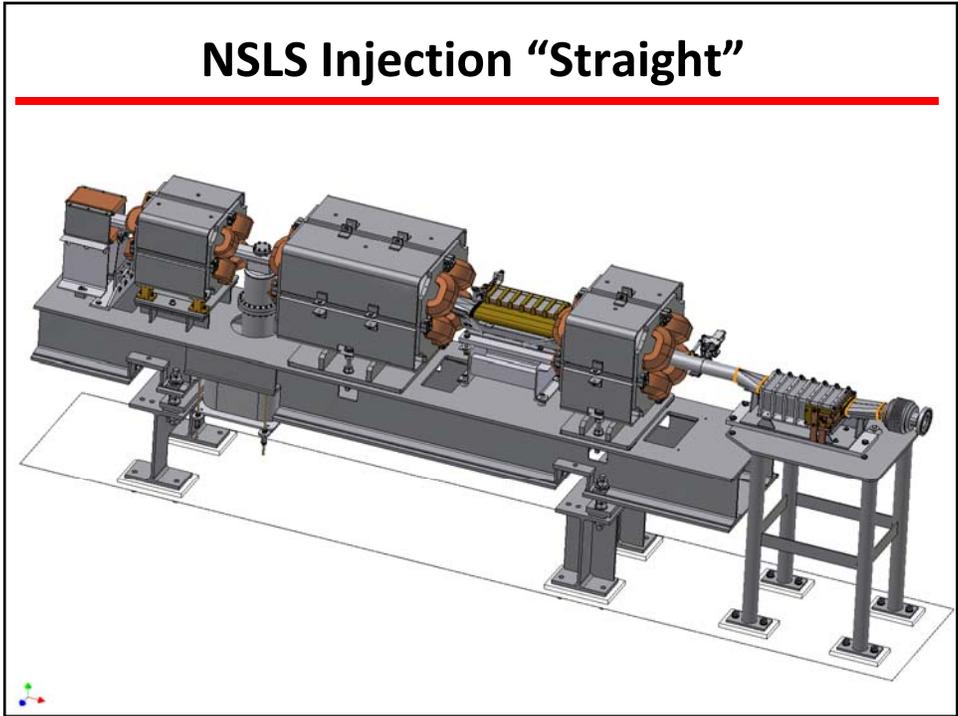

## NSLS Injection Septum Chamber

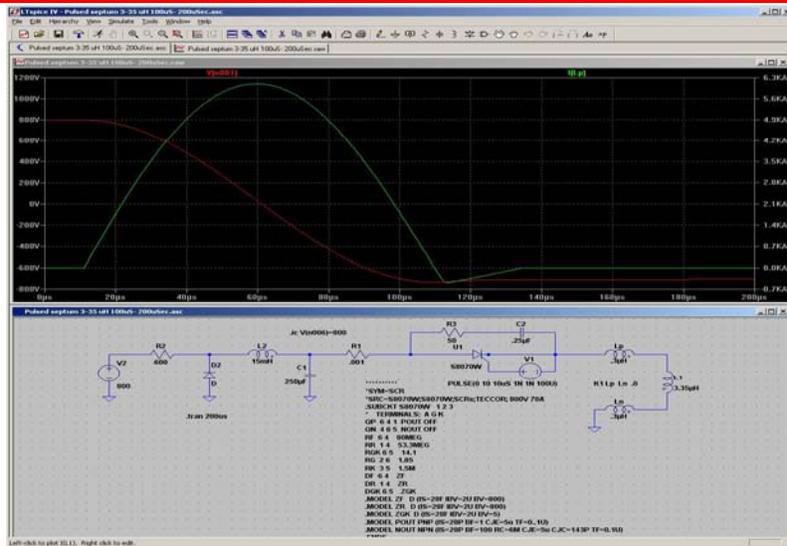

---

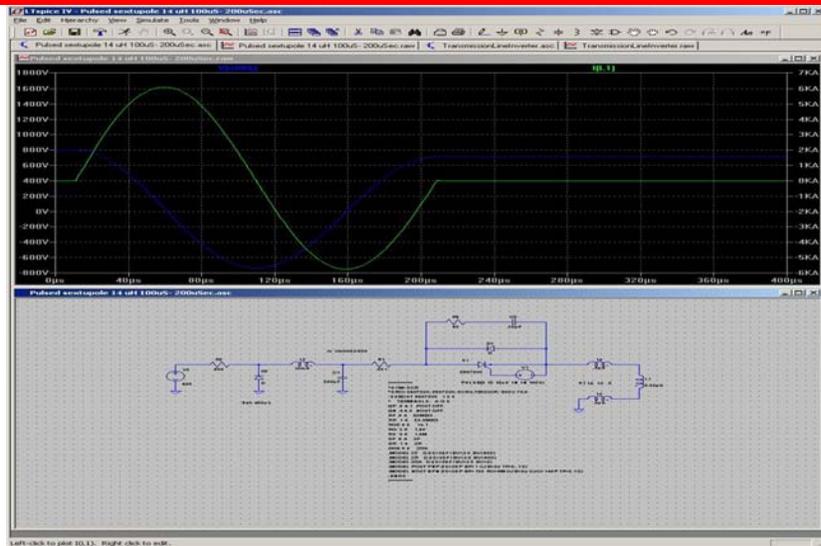

## NLS Injection “Straight”

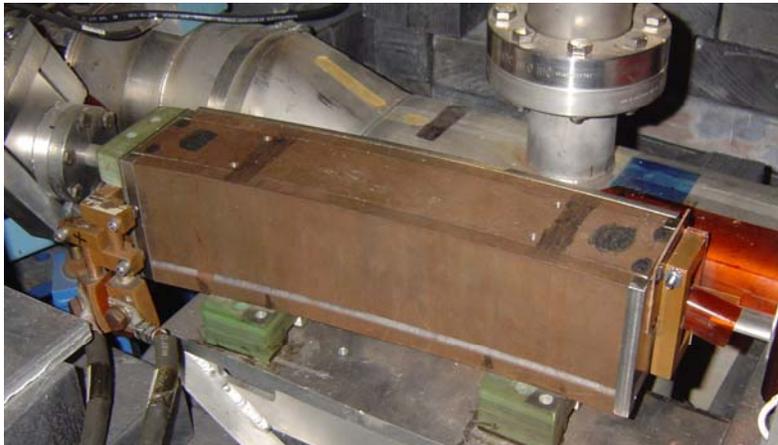

## Modeled Injection Bump

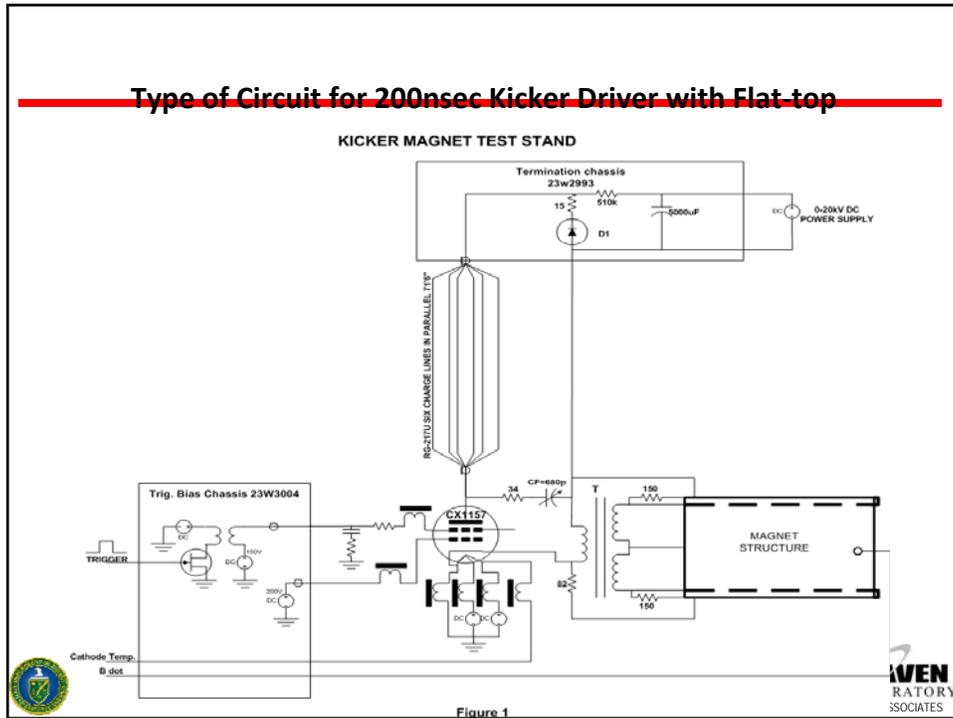

## Modeled Full Sine Wave Septum Pulse

## Extraction Septum

## Type of Circuit for 200nsec Kicker Driver with Flat top

## Septum/Bumps Circuit Topology and Simulations

## NSLS-II Pulsed Sextupole Injection Status

---

Ray Filler  
Pulsed Magnet Workshop  
July 27-28, 2009

1

## Worked on PSM Injection

---

- T. Shaftan, R. Heese, E. Weihreter, F. Willeke, M. Rehak, R. Filler, G. Wang, R. Meier, B. Parker

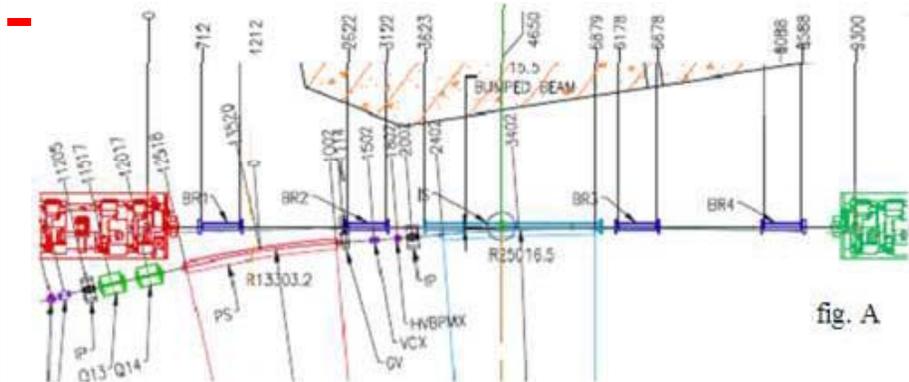

2

## Outline

- Baseline design
- Pulsed Sextupole Injection Scheme
- Design of the sextupole, injection straight and transfer line
- Effect of sextupole on the stored beam
- Storage ring acceptance
- Injected Beam tolerance limits at sextupole
- Transport line tolerances
- Dual pulsed “Distorted Sextupole” or “Triple Dipole” injection scheme
- Other possible injection schemes
- Conclusion

## NSLS-II Baseline Injection System

- Bumps displaces stored beam by 15 mm
- Injected beam leaves the septum displaced 8.5mm from stored beam.
- Beams are parallel at the end of the injection straight, separated by 8.5 mm
- Orbit bumps must be closed enough not to disturb the orbit in the rest of the machine more than  $1/10\sigma$ .

## NSLS-II Pulsed Sextupole Injection System

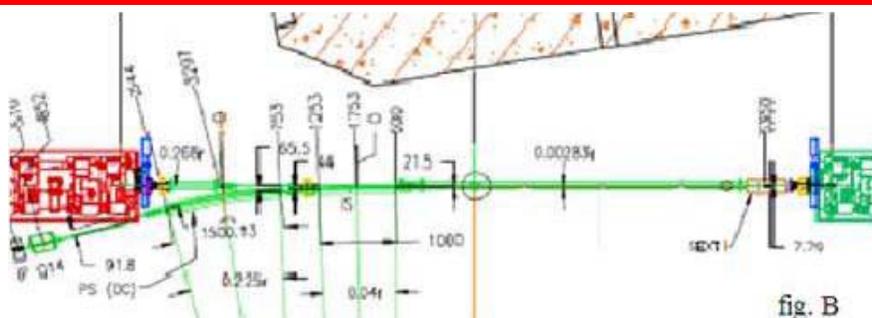

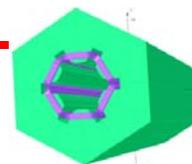

fig. B

- Stored beam goes through the center of the sextupole (downstream end of straight) and receives no kick.
- Pulsed injection septum moved upstream as far as possible.
- Adjusted pre-Septum, additional dipole prior to Q13 (off slide – more later)
- Injected beam arrives at sextupole at 8.5mm from the stored beam (and center of sextupole)
- Sextupole produces a 2.83mrad kick so injected beam is parallel to stored beam.

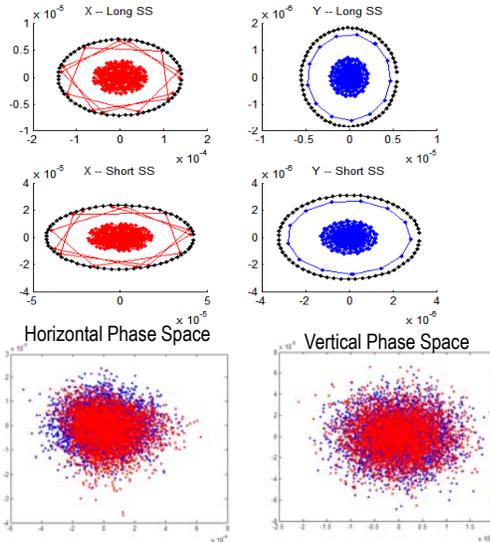

## Magnet Parameters

Parameter	DC septum	Pulsed septum	PSM
Length, m	1.5	1	0.5
Field or gradient	1.5 T	0.4 T	1550 T·m <sup>-3</sup>
Angle, mrad	225	40	2.8
½ aperture, mm	5/20	20/15	25/25
Pulse shape/width, μs	DC	sine/100	½ sine 5.2
Flatness/ Field Error tol., %	n/a	0.2/0.2	<1
Align. tol., μm/μm/mrad	100/100/ 0.2	100/100/ 0.2	100/10/1
Inductance, μH	n/a	3.35	14
Current, kA/ Voltage, kV	26400at/ 0.083	5.25/ 0.56	3.2/ 27

- Injection straight optimized to reduce the strength of the sextupole as much as possible while maintaining requirement that injected beam is 8.5mm from stored beam.
- Magnet design optimized to lower inductance of sextupole as much as possible
- Alignment tolerances for sextupole determined by stored beam motion (next slide)

## Sextupole effect on stored beam

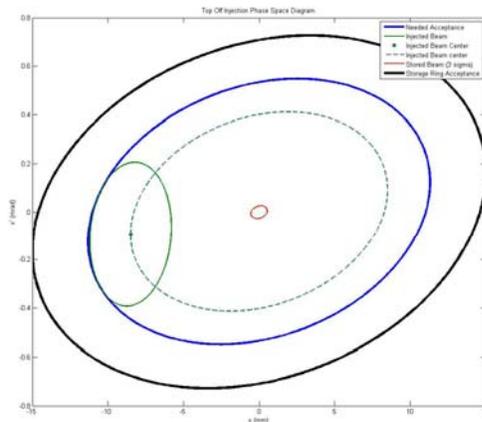

- The black dots show the RMS beam phase space at the center of the long and short straight sections. The red and blue dots show the beam centroid at each source location in the ring. The centroid position moving less than  $1/10^{\text{th}}$  of the beam size

- The effect of the sextupole on the horizontal (left) and vertical (right) phase spaces. The blue dots show the unperturbed phase space. The red dots show the perturbed phase space. Very little distortion is seen.

## Optimal Twiss Functions for TOI

- Twiss functions for injected beam should be chosen to minimize the acceptance needed by the injected beam.
  - In vertical plane this means that the injected beam twiss functions should match the stored beam functions
  - A. Streun worked out what the injected beam twiss functions should be for SLS. (Technical Note SLS-TME-TA-2002-0193)
  - We extended his theory to include nonzero  $\alpha$  so that it can be applied to sextupole injection (NSLS II Technical Note 59)
  - If twiss functions are computed at the end of the injection straight, they are independent of the injection scheme.

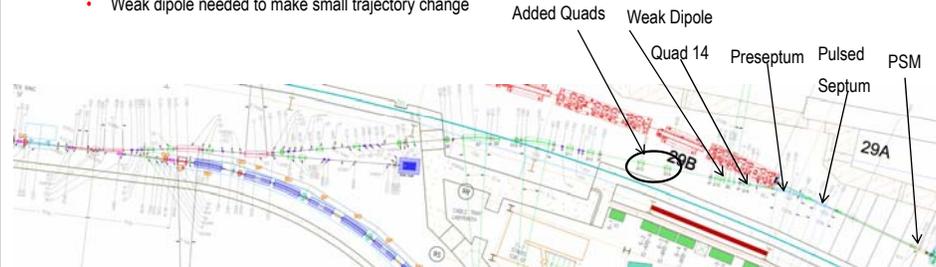

- Most of the acceptance needed for the injected beam is taken up by the offset. (dotted green ellipse)
- Twiss functions of injected beam optimized to minimize the total acceptance (blue ellipse)
- The storage ring dynamic aperture is the maximum acceptance we can use (black ellipse)

Stored Beam	Injected Beam
$\beta_x=21.4$	$\beta_x=9.1$
$\alpha_x=-0.23$	$\alpha_x=-0.1$
$\beta_y=9.8$	$\beta_y=9.8$
$\alpha_y=-1.4$	$\alpha_y=-1.4$

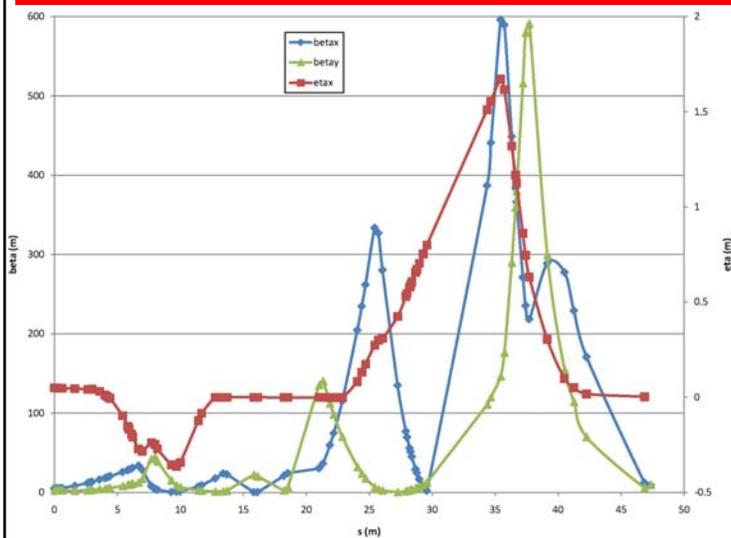

## Transport Line Design

- The sextupole has a gradient of  $1550 \text{ T/m}^2$  and is  $0.5 \text{ m}$  long
- At  $8.5 \text{ mm}$  this gives an effective dipole field of  $56 \text{ mT}$ , and a gradient of  $13 \text{ T/m}$ .
  - The gradient is on the same order as other quadrupoles in the transfer line.
- This has ramifications for transfer line and tolerances
  - Beta functions get large because of long drift ( $9 \text{ m}$ ) between last quadrupole and the sextupole.
  - Moving quads closer is not an option
  - Gradients in preseptum and pulsed septum are impractical due to high fields
  - Moving the injected beam out and reducing the sextupole strength will run into dynamic aperture.
- Other modifications
  - Additional 2 quads needed to control beta function
  - Weak dipole needed to make small trajectory change

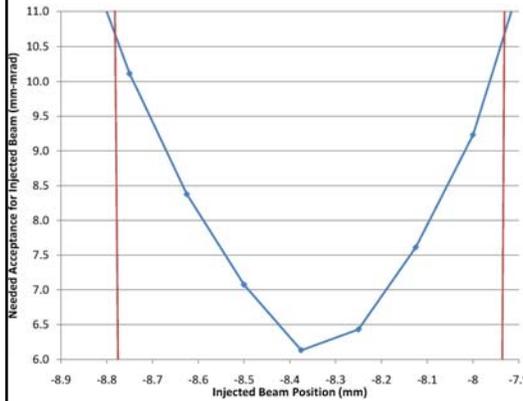

## Twiss Functions

- Sextupole gradient forces  $\beta$  functions to be highest as final 2 quads.
- The maximum  $\beta$  functions for the four bump injection scheme is about  $60 \text{ m}$

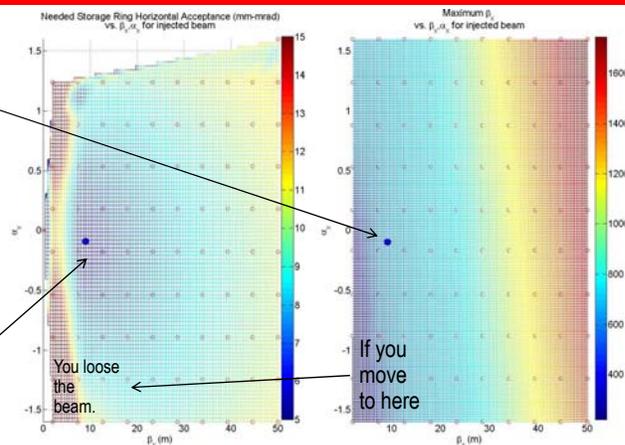

## Tolerance limits on injected beam position

- Changes in the injected beam position at the entrance of the sextupole will lead to
  1. Change in dipole kick and gradient in sextupole.
  2. Change in output angle
  3. Change in output position
  4. Change in output twiss functions
  5. More required acceptance.
- The blue line is the acceptance vs. change in injected beam position.
- The red lines show the position when the injected beam hits the max acceptance of the storage ring (black ellipse)
- The beam can move  $-300 \mu\text{m}$  and  $+500 \mu\text{m}$  before the injected beam needs the entire storage ring acceptance.

## Can the large $\beta$ functions be reduced?

- No.
- Decreasing the max  $\beta$  function required decreasing  $\beta$  for the injected beam at the end of the injection straight, and making a large negative  $\alpha$ .
- This quickly increases the required acceptance beyond the maximum.
- Yellow on these scales is the black ellipse in the acceptance phase space

## Transport Line Tolerances

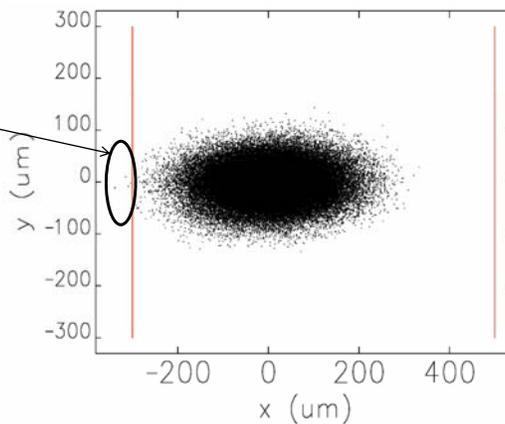

Static (Time Independent) error		Jitter (Time Dependent) error	
Dipole field error	0.1%	Booster extraction kicker	0.2%
Quads field error	0.1%	Booster extraction septum	0.02%
All magnet and BPM roll error	2 mrad	Storage ring pulsed septum	0.02%
Quads transverse misalignment	0.15mm	DC dipole power supply	0.002%
Dipole longitudinal misalignment	1 mm	DC quads power supply	0.01%
Quads longitudinal misalignment	1 mm	Booster beam position	15um
BPM transverse misalignment	0.1 mm	Booster beam angle	10urad
BPM transverse misalignment before PSM	0.025 mm		

Tolerances in red are difficult or impossible to achieve. All have a large effect on the beam position at the pulsed sextupole magnet.

The storage ring pulsed septum needs to meet or exceed this tolerance. This is on the edge of not meeting specification.

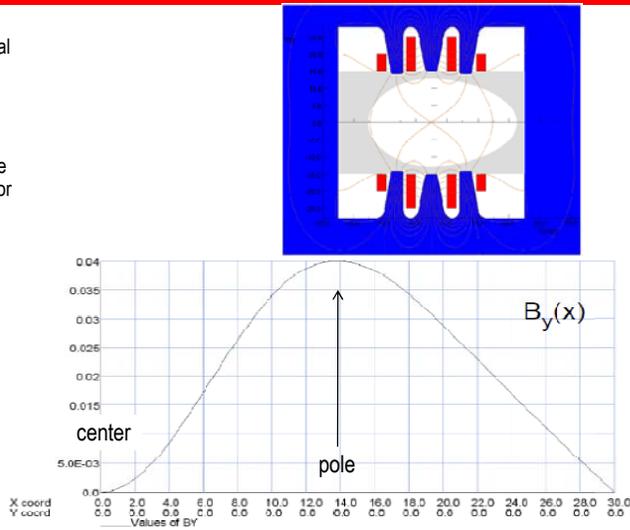

## Effect at Sextupole

- The effect of these tolerance on the beam position at the sextupole.
- Some seeds start to fall out of tolerance.
- An increase in any tolerance will make it difficult to make this scheme work.
- These tight tolerances on the transfer line are causing us to consider abandoning the sextupole injection idea

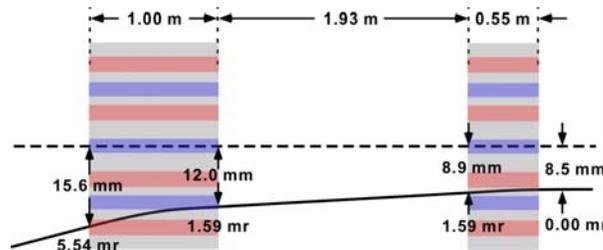

## Brett's "Triple Dipole"

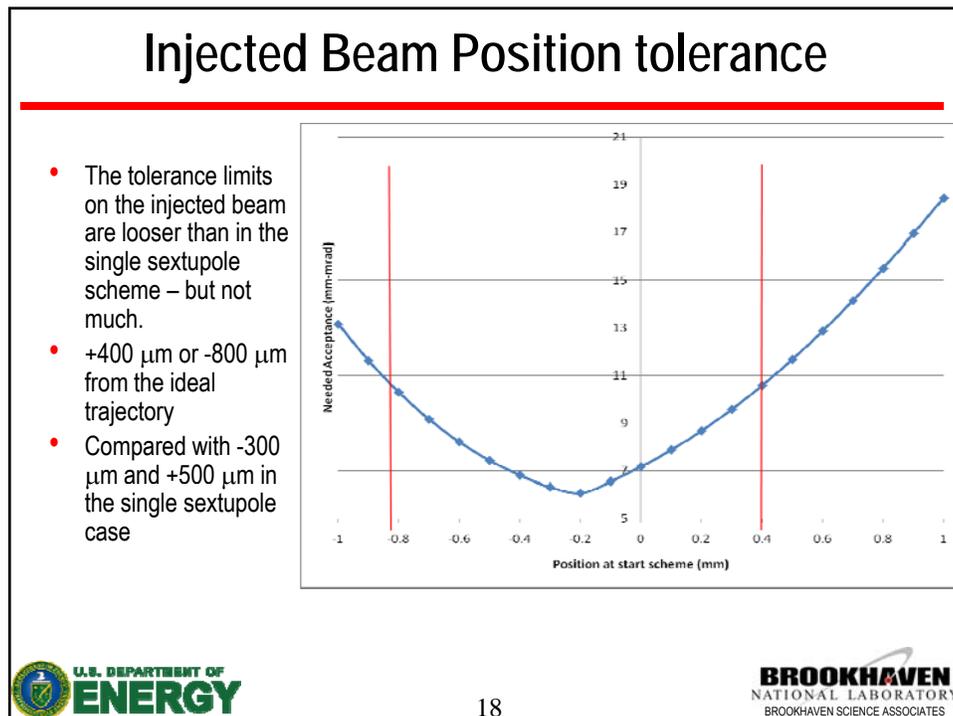

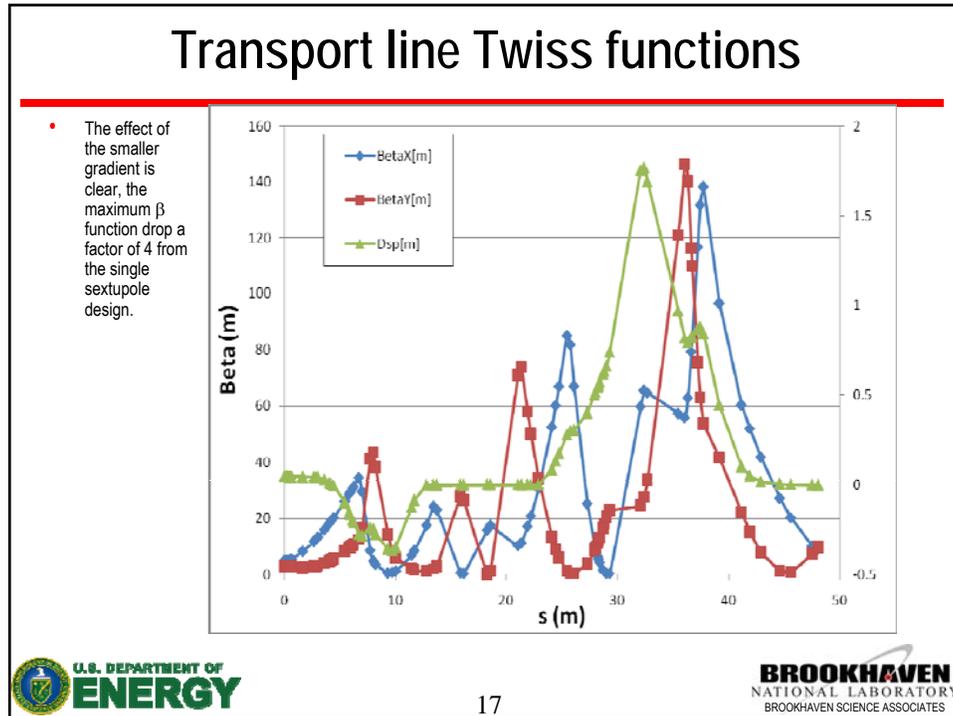

- Brett Parker designed this sextupole magnet with the goal of getting field maximum near the injected beam location to reduce the gradient that the injected beam sees.
- The maximum field is not quite what is needed for the kick, nor is it practical to place the field maximum any closer to the center of the magnet.
- The field in some parts of the iron approach 1 T.
- The field in the center is sensitive to the gap in the middle poles. This will be difficult to shim.
- Two of these can be used for the injection system.

## Injection straight with Brett's "Triple Dipole"

- The first magnet produces a kick with a little defocusing.
- The second magnet finishes removing the angle and provides focusing. The focusing is about  $\frac{1}{2}$  of the sextupole.
- Transport line unchanged from sextupole design.

## Transport line Tolerances

Static error		Jitter Error	
Dipole field error	0.1%	Booster extraction kicker	0.2%
Quads field error	0.2%	Booster extraction septum	0.03%
All magnet and BPM roll error	2 mrad	Storage ring pulsed septum	0.03%
Quads transverse misalignment	0.15mm	DC dipole power supply	0.003%
Dipole longitudinal misalignment	1 mm	DC quads power supply	0.1%
Quads longitudinal misalignment	2 mm	booster beam position	15 $\mu\text{m}$
BPM transverse misalignment	0.1 mm	booster beam angle	6 $\mu\text{rad}$
BPM transverse misalignment before the 1 <sup>st</sup> sextupole	50 $\mu\text{m}$		

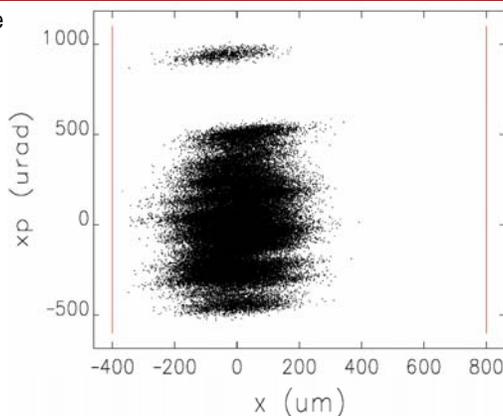

Tolerances in green are looser than in the single sextupole case.

Tolerances in black are identical to single sextupole case.

Tolerances in red are still difficult to achieve.

## Horizontal Phase Space at entrance

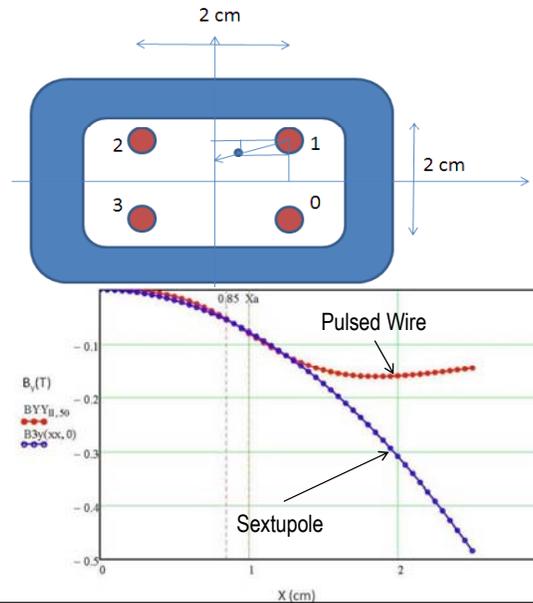

- This is the horizontal phase space at the entrance of the double sextupole
- There are a few shots outside of tolerance.
- The angle change was not included in the tolerance calculation, but is large enough to have a negative effect on the acceptance. This will tighten the tolerances
- This does not include the effect of misalignment or jitter in the sextupoles themselves. This will also tighten tolerances.
- The effect on the stored beam has not been evaluated.

We are no longer considering this option because there are serious doubts about the ability to accurately build these magnets and it will be difficult to commission and operate reliably. Tolerance limits on the transfer line are only marginally improved.

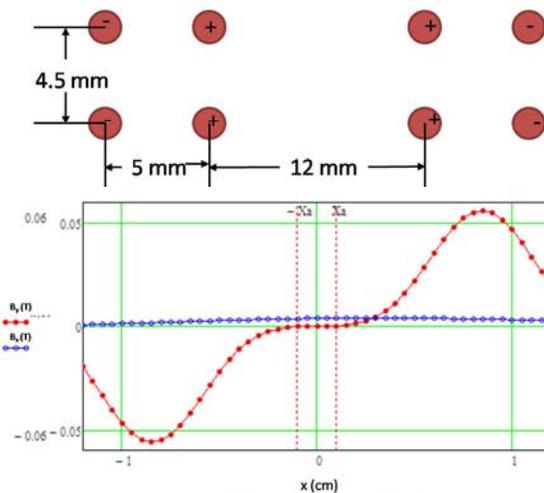

## Pulsed Wires

- P. Kuske to use pulsed wires to generate the necessary field at the injection point.
- To get the flat part of the field near where the injected beam is, the wires have to be closer together. This is a concern.

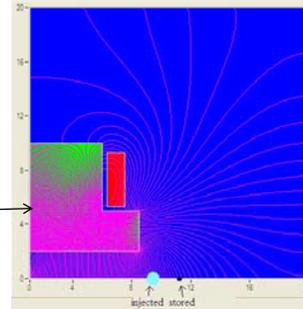

## "Ferdinand's Wires"

- Ferdinand Willike came up with an 8 wire configuration
- This places the field maximum near the injected beam
- The field is flat near the stored beam.
- But still, the wires are very close to the beams.

## Other Miscellaneous Ideas

- Sextupole in Another Straight
  - Rejected because it takes up user space, and may cause losses in the intervening cells
- Doublet Sextupole
  - Rejected, only made the large  $\beta$  issue worse. Acts like a doublet quad.
- Mirror septum quad & sextupole
  - Use a mirror septum quad like in the HERA upgrade to steer and focus the injected beam. Desired kick gives the anti-desired gradient. Rejected.
- Sextupole-Octopole combination
  - Use a sextupole superimposed on an octopole to get a low gradient for the injected beam. Both magnets are very powerful for a very weak field. Rejected.
- Edge fields
  - Use the edge of a C magnet to have a strong field at the injected beam and taylor it to have zero field by stored beam. Gradient may be an issue.

## Conclusion

- We have investigated using a pulsed sextupole for NSLS-II injection using two different schemes
- This type of injection seems difficult to do for a variety of reasons
  - Transfer Line
  - Difficult to build (Triple dipole)
- We also investigated a number of alternative ideas, some not impossible, other rejected outright.

## OUTLINE

- I. The Taiwan Photon Source
- II. TPS Injection System and Design Considerations
- III. Booster Injection and Extraction
- IV. Storage Ring Injection
- V. Pulsed Magnet Prototypes and Field Mapping System
- VI. Summary

NSRRC Parameters of TPS Storage Ring	
• Beam energy :	3 GeV
• Beam current:	300 mA (Phase-1)
• Emittance:	1.7 nm-rad
• Lifetime:	> 10 hours
• Straight Sections:	7 m (x18); 12 m (x6)
• Lattice structure:	24 DBA
• Circumference:	518.4 m
• Critical photon energy:	7.13 keV
• RF frequency	500 MHz

## NSRRC *Parameters of TPS Booster*

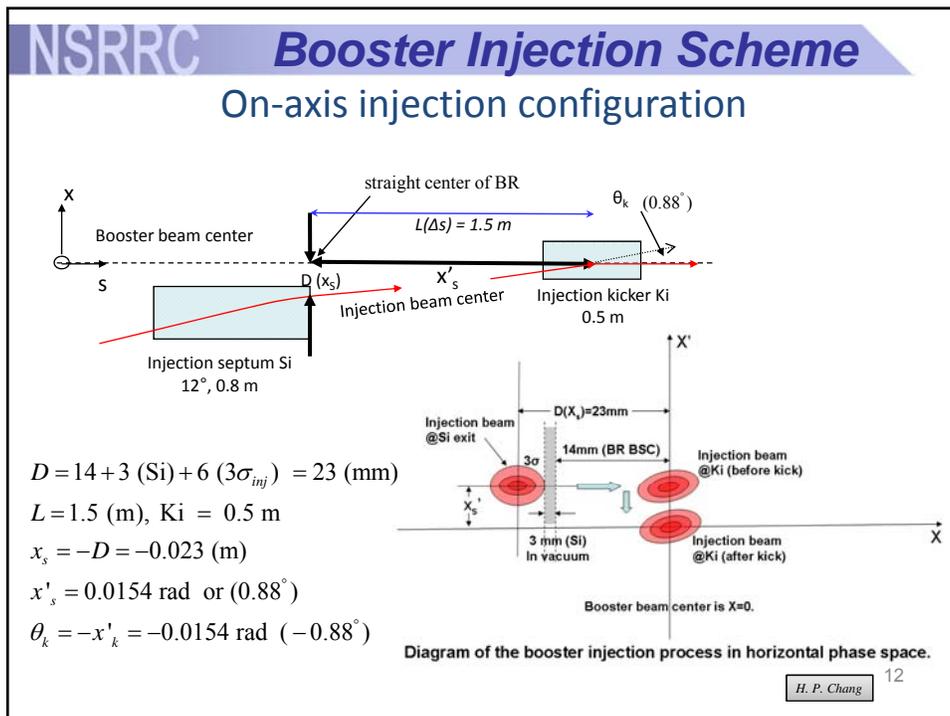

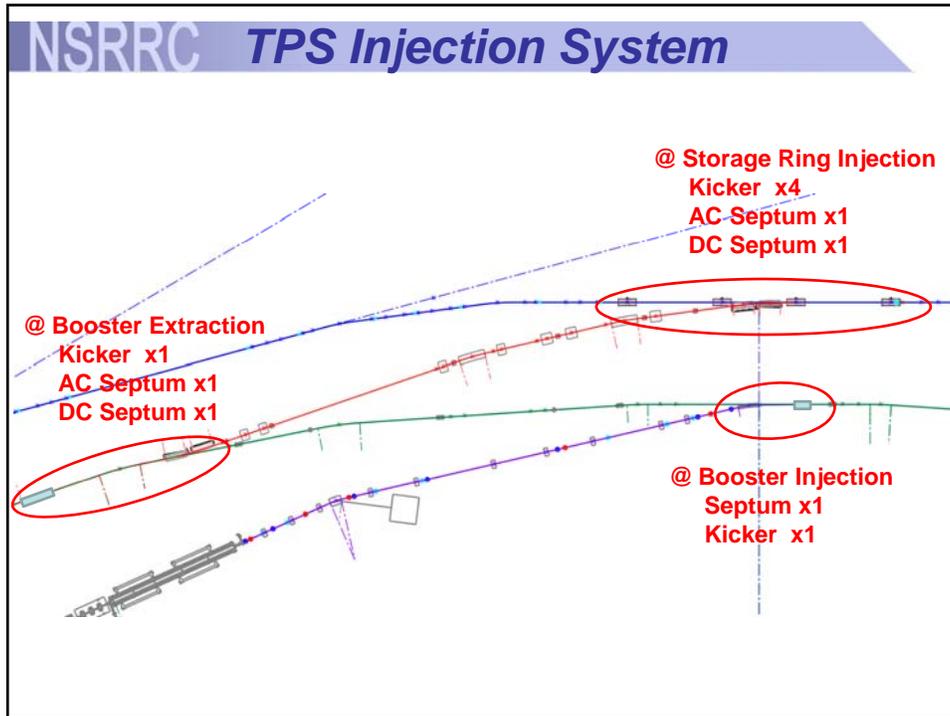

- Injection Energy: 150 MeV
- Extraction Energy : 3 GeV
- Repetition Rate: 3 Hz
  
- Emittance: 10.32 nm-rad
- Straight section: 6 m
- Superperiod: 6
- Circumference: 496.8 m
- Harmonic Number: 828
- RF frequency 500 MHz

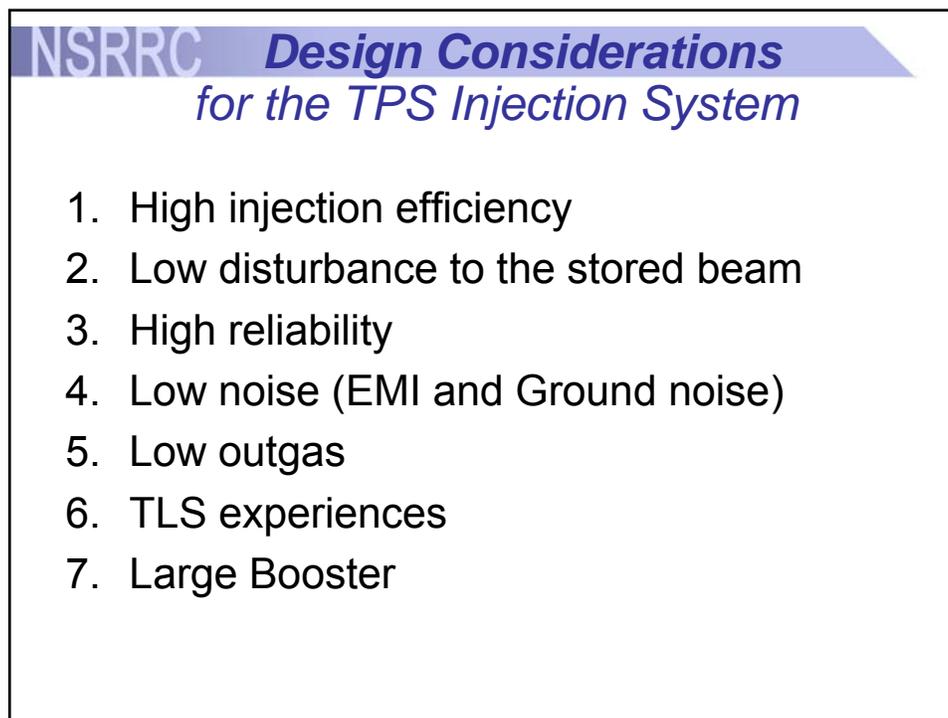

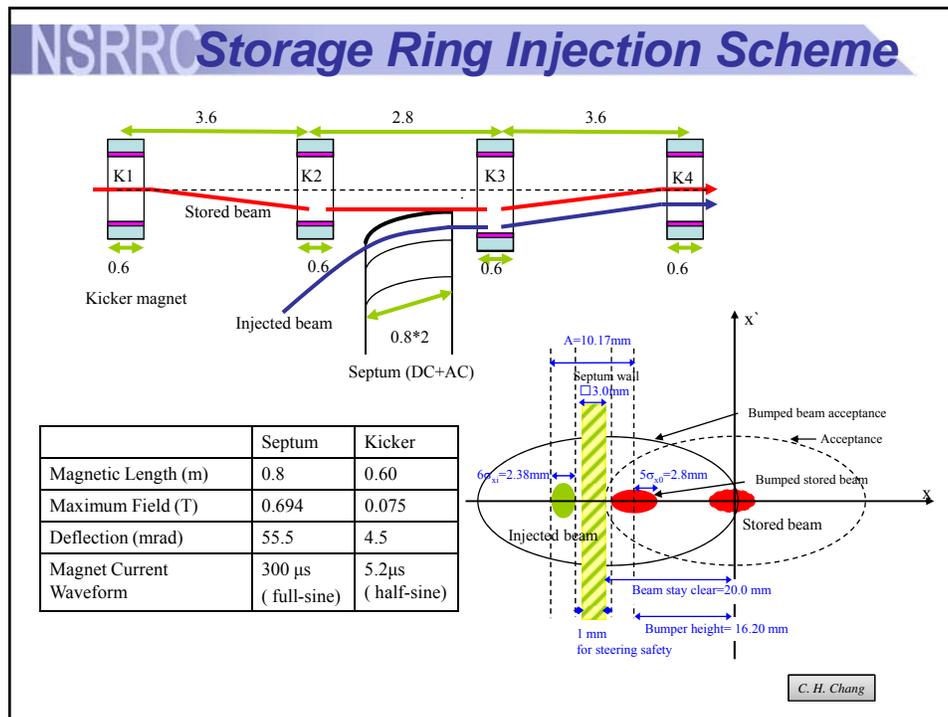

9

## NSRRC *Milestones of TPS Construction*

- Oct. 2007 Lattice approved by BOT  
Architect firm selected
- Dec. 2007 TPS final approval by Legislative Yuan
- June 2008 EPA approval; site plan completed
- June 2008 Accelerator design book issued
  
- Oct. 2009 1/24 ring (one cell) prototype construction
- Dec. 2009 Groundbreaking
  
- July 2012 Starting storage ring installation
- Oct. 2014 Open to users

10

## NSRRC Main Features of the TPS

- **Low emittance and high brightness**
  - Brightness  $>10^{21}$  p/s/0.1%bw/mm<sup>2</sup>/mrad<sup>2</sup> (@ 10 keV)
  - Emittance  $\epsilon < 2$ nm-rad
- **High stability**
  - Photon intensity fluctuation  $<0.1\%$
  - Beam orbit fluctuation  $< 0.2\mu\text{m}$  ( $d\sigma/\sigma \approx 5\%$ )
  - Beam size fluctuation  $< 0.1\mu\text{m}$
- **High reliability**
  - High injection efficiency ( $> 90\%$ )
  - Machine Up-time  $> 98\%$
  - Trip rate  $< 1/\text{week}$
- **Superconducting Technologies**
- **Top-up injection**
- **Same-tunnel Booster**

15

## NSRRC Design Considerations (conti.)

### **Small Field Error**

- Stable power supply (septum & kicker)
- Small time jitter (matching of SR inj. kickers)
- Short rise time and fall time (BR kickers)
- Precise alignment (to reduce horizontal field)
- Stable loads on circuit

### **Low Leakage Field and Field Distortion**

- Septum and shielding material (septum)
- Thickness and uniformity of coating (ceramic chamber)
- Full sine waveform (Injection septum)
- To reduce thermal induced effects (septum & kicker)

## NSRRC *Design Considerations (conti.)*

### **High Reliability**

- Low drive voltage (to reduce breakdown)
- High quality manufacturing (coating, brazing, etc.)
- Reduced heating load  
(on magnets, chamber and circuit components)
- Out-of-vacuum device (septum, also **Low Outgas** )

### **Low Electrical Noise**

- Independent power feeder and grounding line
- EMI shielding

### **To Use the Advantage of a Large Booster**

- Precise condition of the injected beam
- Long bunch train for injection

## NSRRC *Booster Injection and Extraction*

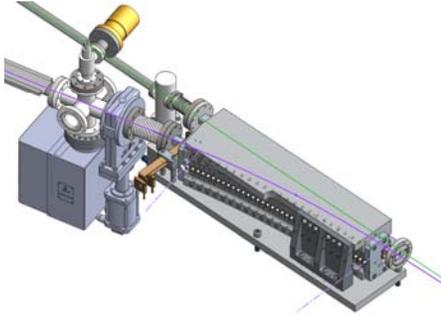

1. Booster Injection Septum
2. Booster Injection Kicker
3. Booster Extraction Septum
4. Booster Extraction Kicker

## NSRRC Booster Injection Septum

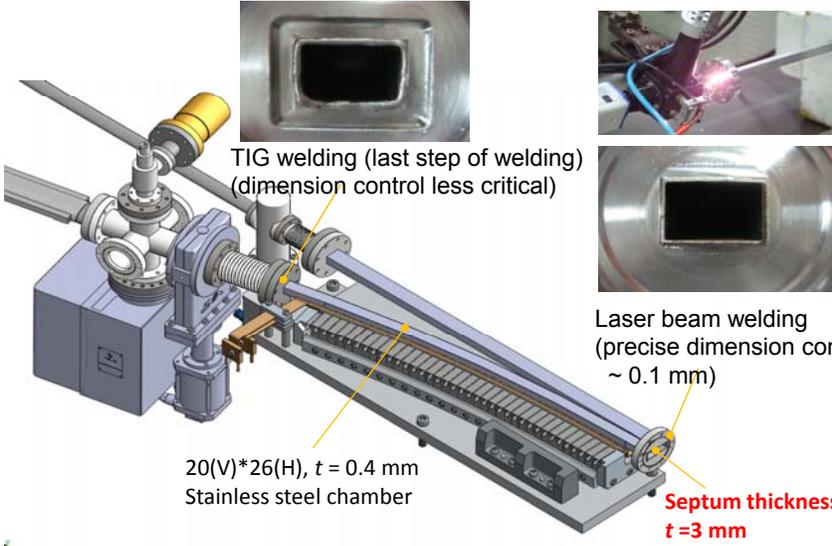

Booster Injection Septum	3 Hz
Electron energy (GeV)	0.15
Bend angle (mrad)	209.44
Mag. aperture (mm)	28*22
Length (m)	0.8
Maximum field (T)	0.131
Bend radius (m)	3.8197
Beam aperture (mm)	26*20
Max. current (A)	2292
Pulse shape	full sine
Pulse duration (us)	300
Energy in magnet (J)	3.36
Impedance (Ohm)	0.027
Inductance (mH)	1.28
Inductance (simulated)	1.95
Capacitance (mF)	1782
Drive voltage (kV)	0.061
Leakage field (%)	< 0.1
Field error (%)	0.5

**Features**

- *Less critical for power supply*  
-- Injection energy is low (150 MeV)
- *Septum (out-of-vacuum)*  
-- easy fabrication for septum  
-- easy fabrication for chamber  
-- 0.4 mm thickness (less heat and field distortion)
- *With shielding to reduce leakage field*

## NSRRC Booster Injection Septum (conti.) (Septum Chamber)

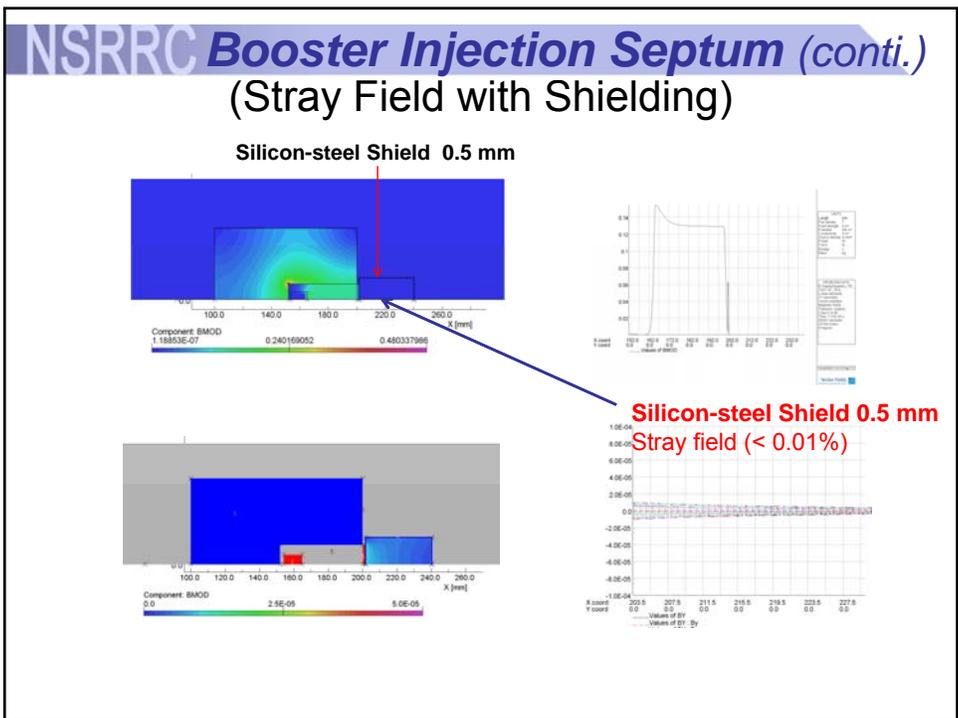

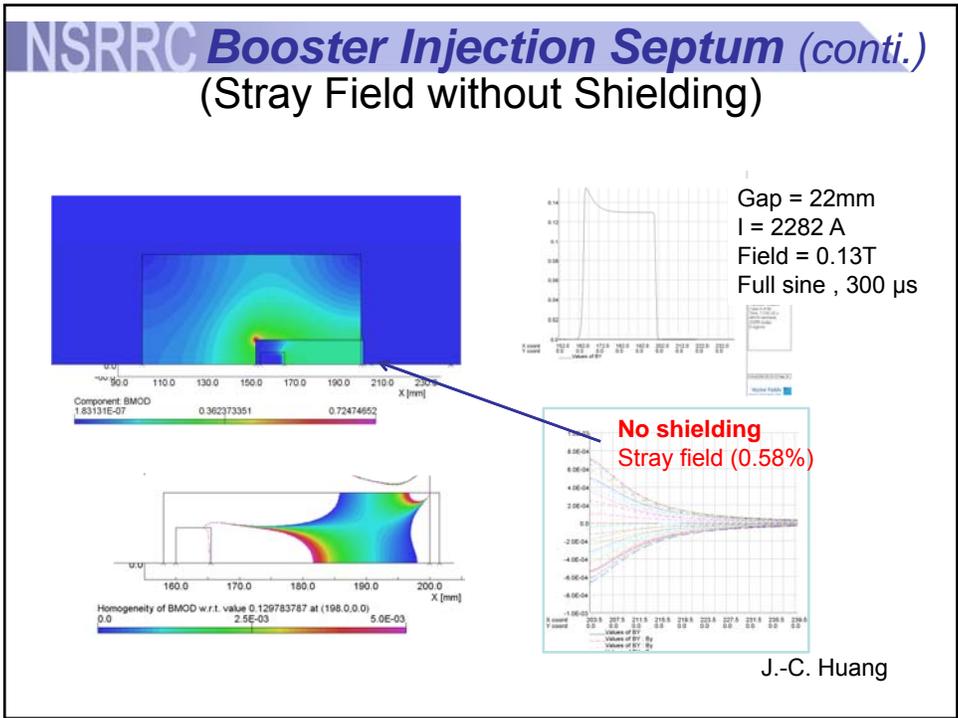

TIG welding (last step of welding)  
(dimension control less critical)

Laser beam welding  
(precise dimension control  
~ 0.1 mm)

20(V)\*26(H),  $t = 0.4$  mm  
Stainless steel chamber

**Septum thickness  
 $t = 3$  mm**

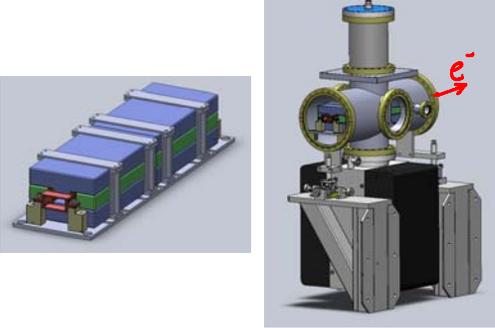

## NSRRC Booster Injection Kicker

BR inj. Kicker	3Hz
Energy (GeV)	0.15
Bend angle (mrad)	16
Mag. aperture (mm)	50*21
Length (m)	0.5
Maximum field (T)	0.016
Bend radius (m)	31.25
Beam aperture (mm)	35*20
Max. current (A)	267
Pulse shape	Flat top
Fall time (ns)	100
Pulse duration (ns)	1000ns-FT
Energy in magnet (J)	0.053
Impedance (Ohm)	25
Inductance (mH)	1.50
Capacitance (mF)	--
Drive voltage (kV)	13.4

### Features

- Less critical for power supply  
-- Injection energy is low (150 MeV)
- Long pulse injection 1000ns
- In-vacuum kicker  
-- Outgassing rate OK, after baking
- PFN circuit

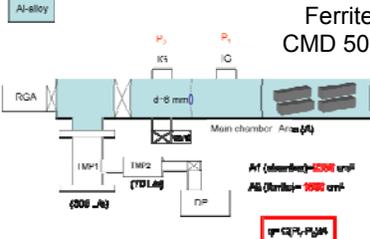

## NSRRC Booster Injection Kicker (conti.)

### (Outgassing Rate of Ferrite)

After baking at 150 °C for 24 hr  
 $P_1 = 2.26 \times 10^{-9}$  torr  
 $q = 1.38 \times 10^{-12}$  torr.L/s.cm<sup>2</sup>

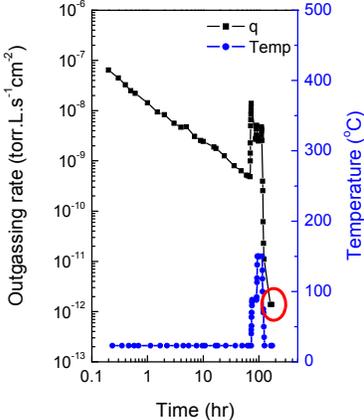

Figure . System for measuring the rate of thermal outgassing

## NSRRC Booster Extraction Septum

BR Extraction AC septum	3Hz
Energy (GeV)	3.0
Bend angle (mrad)	55.5
Mag. aperture (mm)	22*15
Length (m)	0.8
Maximum field (T)	0.694
Bend radius (m)	14.4144
Beam aperture (mm)	20*13
Max. current (A)	8281
Pulse shape	half sine
Pulse duration (us)	150
Energy in magnet (J)	50.6
Impedance (Ohm)	0.031
Inductance (mH)	1.47
Inductance (simulated)	2.85
Capacitance (mF)	1546
Drive voltage (kV)	0.302
Leakage field (%) (DC)	<0.01%
Field error (%)	< 1

### Features

- Septum AC+DC
  - to reduce the field of AC septum
- DC septum
  - double layer shielding
- AC Septum
  - out-of-vacuum
  - easy fabrication for septum and chamber
  - 0.4 mm thickness (less heat and field distortion)

## NSRRC Booster Extr. Septum (conti.)

## NSRRC SR Injection Septum

AC septum	3Hz
Energy (GeV)	3.0
Bend angle (mrad)	55.5
Mag. aperture (mm)	22*15
Length (m)	0.8
Maximum field (T)	0.694
Bend radius (m)	14.4144
Beam aperture (mm)	20*13
Max. current (A)	8281
Pulse shape	full sine
Pulse duration (us)	300
Energy in magnet (J)	50.6
Impedance (Ohm)	0.031
Inductance (mH)	1.47
Inductance (simulated)	2.85
Capacitance (mF)	1546
Drive voltage (kV)	0.302
Leakage field (%) (AC)	< 0.1%
Field error (%)	1

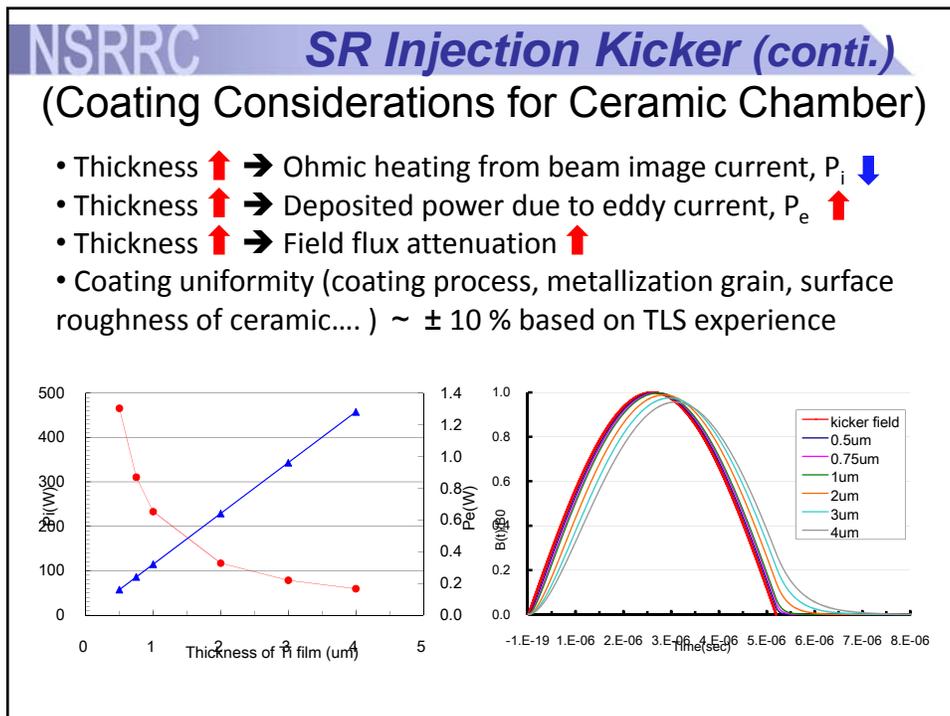

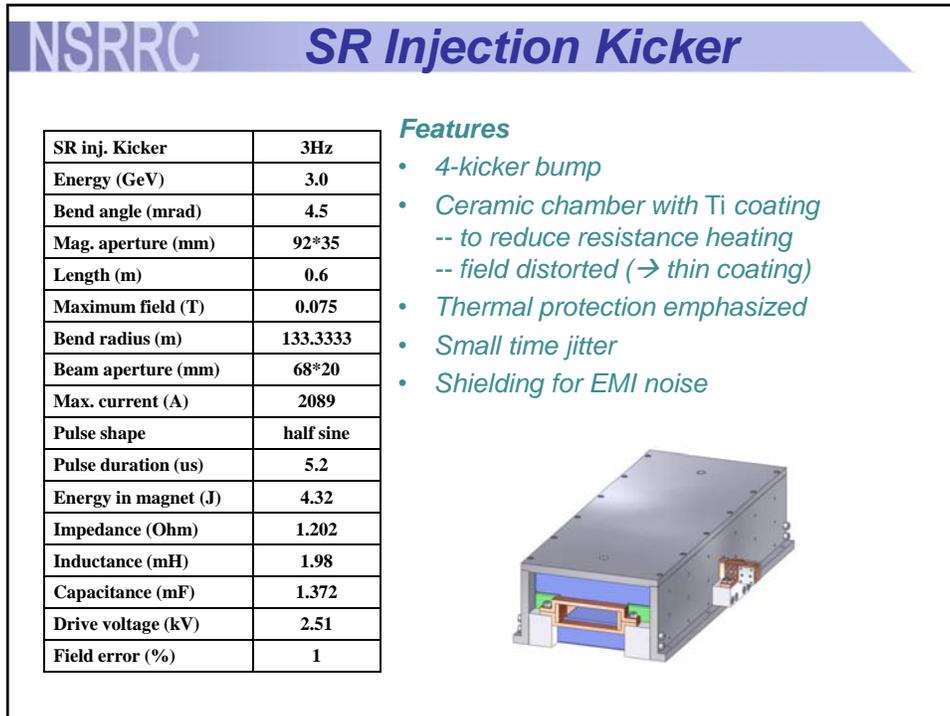

**Features** (similar to the booster ext. septum)

- Septum AC+DC  
-- to reduce the field of AC septum
- DC septum  
-- double layer shielding
- AC Septum (out-of-vacuum)  
-- easy fabrication for septum and chamber  
-- 0.4 mm thickness (less heat and field distortion)

HV-power supply
Kicker pulser box
Kicker magnet

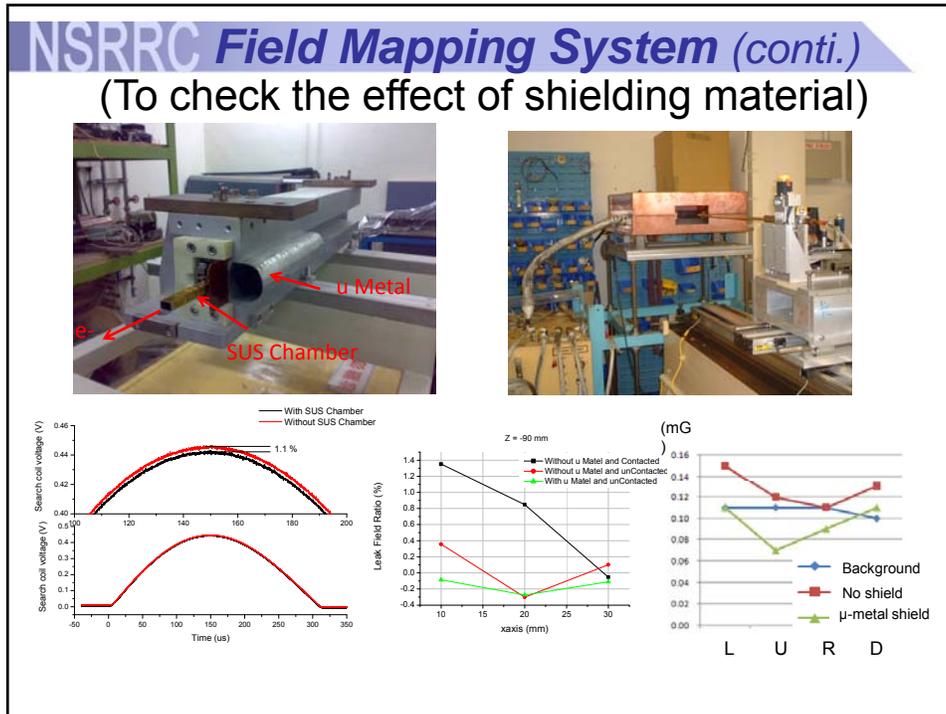

39

## NSRRC Field Mapping System

## Summary

1. Pulsed magnet system for the TPS have been designed.
2. High injection efficiency, low disturbance to the stored beam, high reliability of the components, low noise, low vacuum outgas and the experiences gained at TLS are considered in the design.
3. Techniques to reduce the stray field, field distortion, thermal effect, noise, and time jitter are studied and applied to the design of the TPS injection system.
4. Field mapping system and prototypes for the TPS pulsed magnets are under testing.

Thank you for your attention.

# Design and field measurement of the PSM at the PF-ring

Hiroyuki Takaki

Institute of Solid State Physics (ISSP),  
University of Tokyo

---

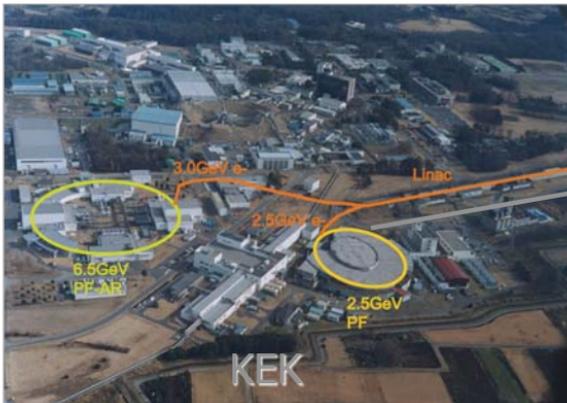

---

## Outline

- Principle of the Pulsed Sextupole Magnet (PSM) injection
    - Differences from the conventional injection
    - How does the PSM work?
  - Design of the PSM as an application for the PF-ring
  - Field measurements
- 
- Installation
  - Multi-particle simulation
  - Experimental results
  - Case study of NSLS-II injection
- > Next talk

---

## Photon Factory (PF) and Photon Factory Advanced Ring (PF-AR)

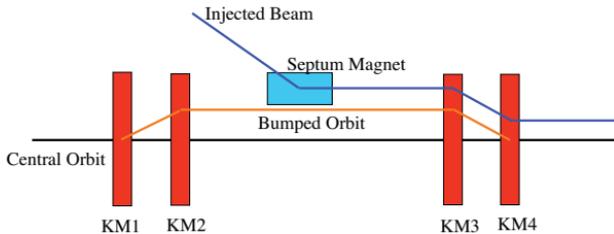

116

---

3

---

## Conventional Injection Using Bumped Orbit

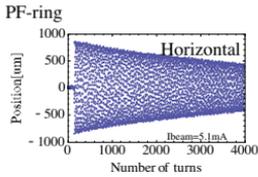

- To reduce **coherent dipole oscillation** of an injected beam
- Imperfection of the bumped orbit
  - field errors, timing jitters and mismatch of injection kickers
  - non-linear magnetic field like sextupole magnets inside the bump

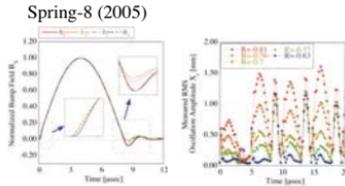

---

4

## Examples of Stored Beam Oscillation in beam injection

Mismatch of the injection kicker magnets.

"Suppression of injection bump leakage caused by sextupole magnets within a bump orbit", H. Tanaka et al., Nucl. Inst. Meth. A 539, 547 (2005).

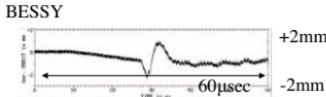

Figure 2. Transient horizontal orbit distortions of the stored beam measured bunch-by-bunch induced by the stray field of the septum and the mismatch of the injection kicker magnets. The amplitude of the vertical orbit distortion reaches also 1 mm.

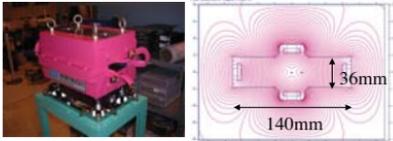

P. Kuske et al., Proc. of the EPAC 2008, Genoa, p2067.

5

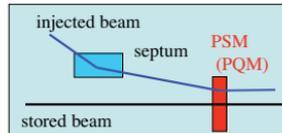

117

## Beam Injection with Pulsed Multi-pole Magnets

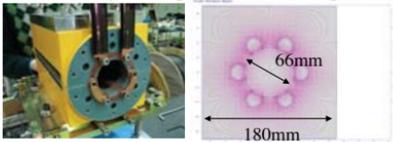

Pulsed Quadrupole Magnet: PQM (PF-AR 2004~)

"New injection scheme using a pulsed quadrupole magnet in electron storage rings", K. Harada, Y. Kobayashi, T. Miyajima and S. Nagahashi, Phys. Rev. ST Accel. Beams 10 123501 (2007).

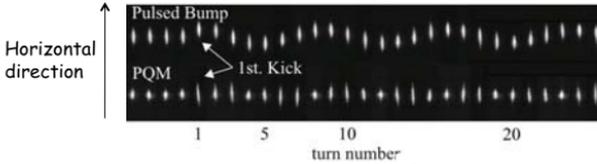

Pulsed Sextupole Magnet: PSM (PF-ring 2008~)

6

# Stored Beam Profile (PQM Injection at the PF-AR)

fast gated camera

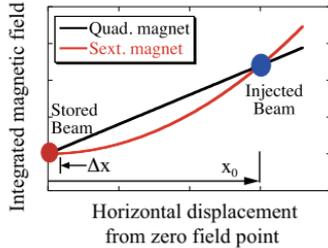

PQM Injection:  
beam oscillation → small

But, stored Beam is Blinking!  
Quadrupole Mode Oscillation?

To reduce the effect to the stored beam,  
we selected the PSM at the PF-ring.

$$\frac{B_{y,s}}{B_{y,Q}} = \frac{\Delta x}{x}$$

7

118

## PSM injection in normalized phase space

$$\theta = \frac{1}{2} K_2 x^2$$

$$W = X^2 + P^2$$

$$X_2 = X_1 = \frac{x_1}{\sqrt{\beta_1}}$$

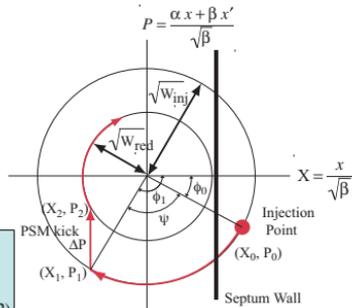

$$P_2 = \frac{1}{\sqrt{\beta_1}} \{ \alpha_1 x_1 + \beta_1 (x_1' + \theta) \} = P_1 + \sqrt{\beta_1} \theta$$

$$\Delta P = P_2 - P_1 = \sqrt{\beta_1} \theta = \frac{1}{2} \beta_1^{3/2} K_2 X_1^2 \dots (1)$$

$$|\Delta P| = |P_1| - |P_2| = \sqrt{W_{inj}} |\sin \phi_1| - \sqrt{W_{red} - W_{inj}} \cos^2 \phi_1 \dots (2)$$

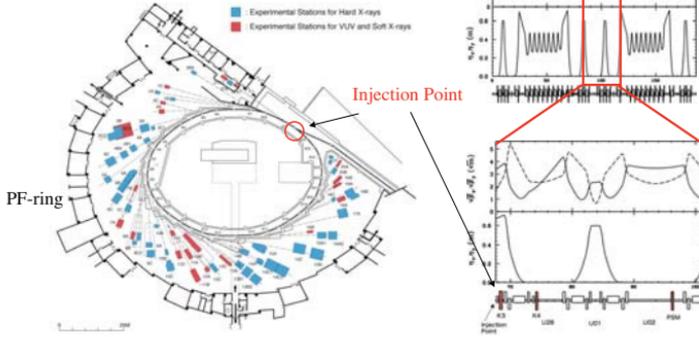

$$|K_2| = \frac{2 \left( \sqrt{W_{inj}} |\sin \phi_1| - \sqrt{W_{red} - W_{inj}} \cos^2 \phi_1 \right)}{\beta_1^{3/2} W_{inj} \cos^2 \phi_1} \dots (3)$$

$$K_2 (W_{inj}, W_{red}, \phi_1, \beta_1)$$

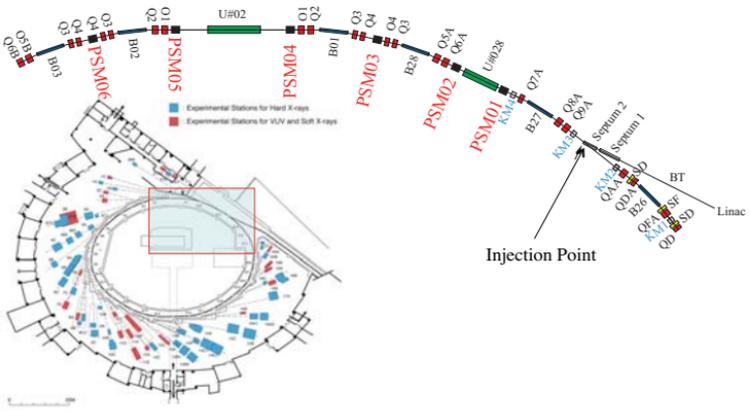

8

### PF-ring

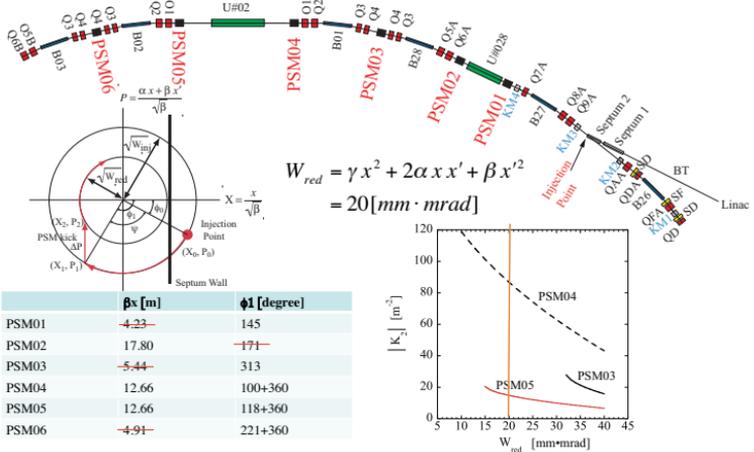

9

### Installation candidates at the PF-ring

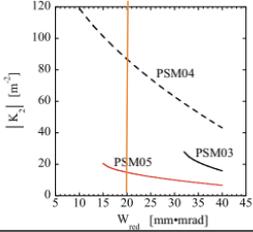

10

## Installation candidates at the PF-ring

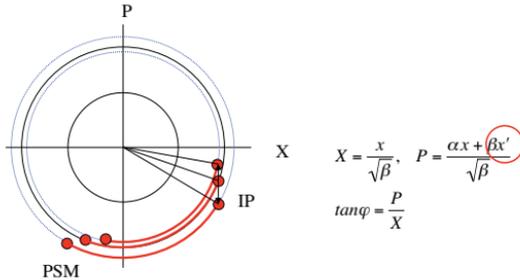

$$W_{red} = \gamma x^2 + 2\alpha x x' + \beta x'^2 = 20[\text{mm} \cdot \text{mrad}]$$

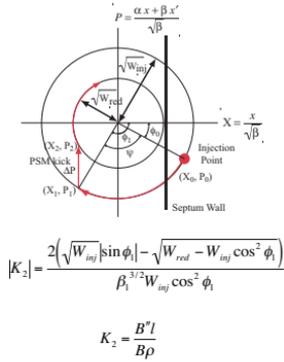

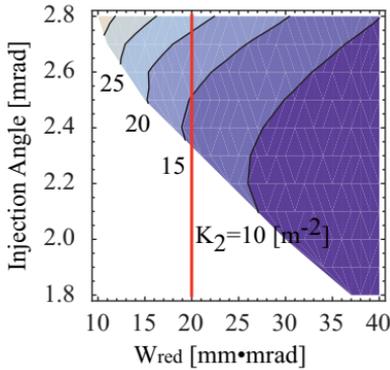

## Tunability of PSM Position in Phase Space

- (1) Changing phase advance  $\rightarrow$  betatron function
  - may change the operating tune
  - may break periodicity of the ring optics
- (2) Changing injection angle ( $x'$ )  $\rightarrow$  septum kick angle

## $K_2$ as a function of reduced injection amplitude and injection angle

121

13

## PSM parameters (PF-ring)

$$K_2 = \frac{B''l}{B\rho} = 13 [m^{-2}]$$

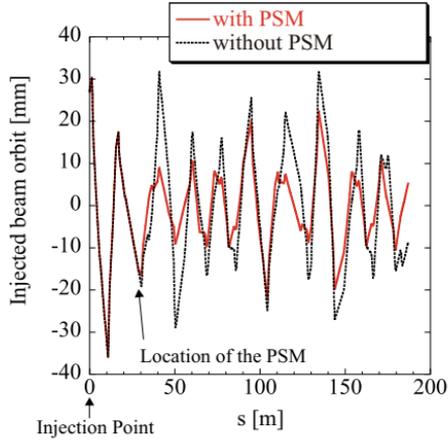

$$E_{beam} = 2.5 [GeV]$$

$$B'' = \frac{K_2 E_{beam}}{0.3l} = 416 [T/m^2] @ L = 0.3m$$

$$ByL = \frac{1}{2} B'' x^2 L \sim 120 [G \cdot m] @ x = 15mm$$

---

## SUMMARY

- Design and Fabrication of the PSM was done.
- The magnetic field satisfied the requirement.
- Next step is whether the PSM injection system will work well.

# Results of the PSM operation at the PF-ring

**Hiroyuki Takaki**

Institute of Solid State Physics (ISSP),  
University of Tokyo

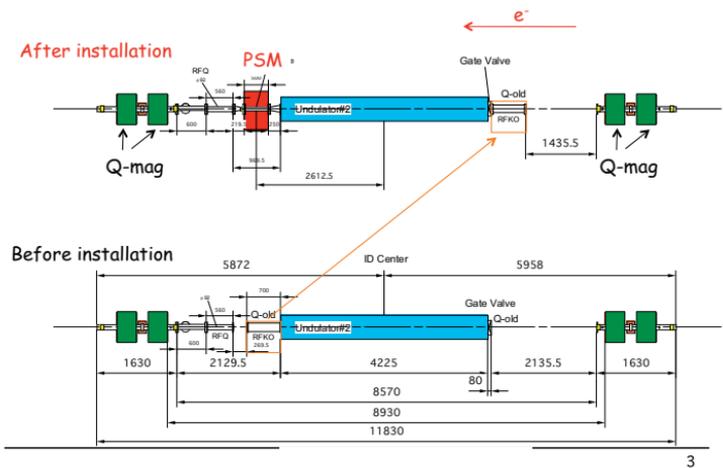

---

---

## Outline

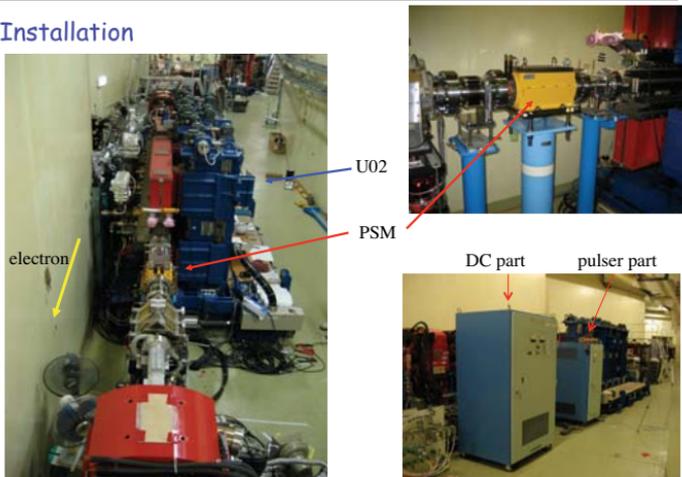

- Installation of the PSM
- Multi-particle tracking simulations
- Latest experimental results of the PSM injection
- NSLS-II case study (single particle simulation)

## PSM installation

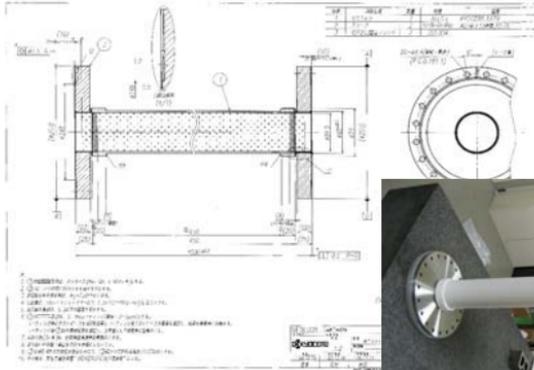

131

## Installation

Ceramic chamber  $Al_2O_3$

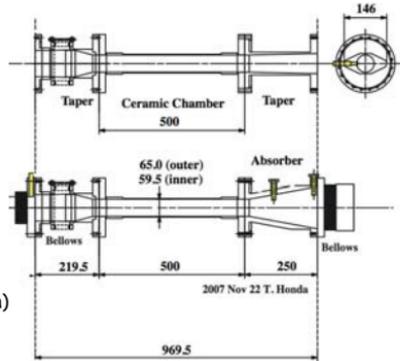

5

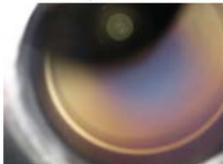

Ceramic chamber

Ceramic Chamber (white)  
100µm thick protection film (brown)

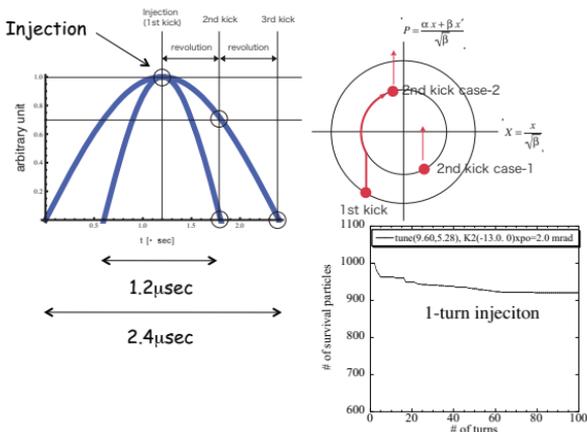

PSM core length 300mm

The inner side is coated with a titanium layer of 3 µm thick

6

## 2-turn injection (specific problem of the PF-ring)

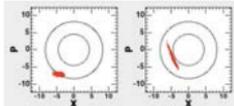

133

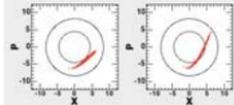

7

## Example of 2-turn injection

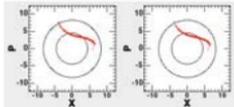

Before kick Just after kick

1st turn

2nd turn

3rd turn

$$X = \frac{x}{\sqrt{\beta}}, \quad P = \frac{\alpha x + \beta x'}{\sqrt{\beta}}$$

$K_2=10 \text{ [m}^{-2}\text{]}$   
 # of particles: 1000  
 emittance  
 $x: 150 \text{ nm}\cdot\text{rad}$   
 $y: 150 \text{ nm}\cdot\text{rad}$   
 $z: 12 \text{ mm}\cdot\text{rad}$

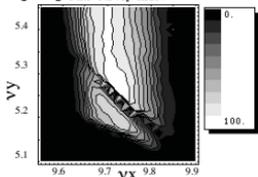

Septum Kick Angle 1.7mrad  
 Timing Delay 467nsec

8

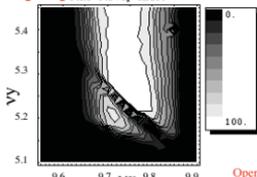

## Optimum operating tune for the PSM injection

$$K_2 = \frac{B'L}{B\rho} [m^{-2}]$$

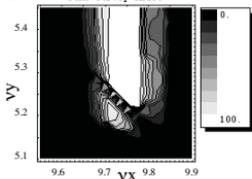

$K_2=17[m^{-2}]$  Tune Survey K2=17

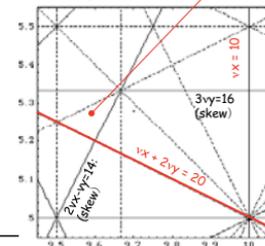

$K_2=13[m^{-2}]$  Tune Survey K2=13

$K_2=10[m^{-2}]$  Tune Survey K2=10

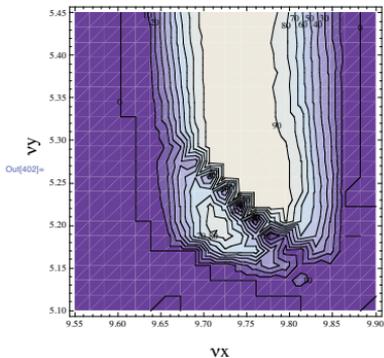

Operating Tune(9.60, 5.28)

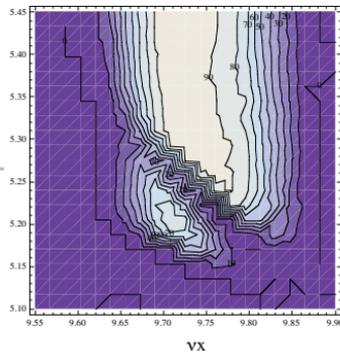

9

## COD correction

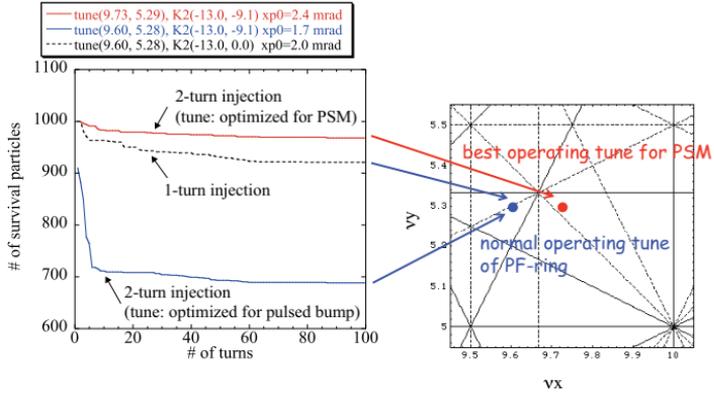

After correction

Before correction

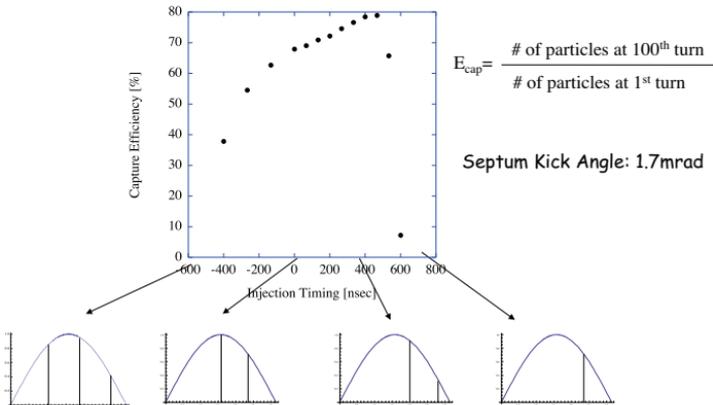

## Operating point for the PSM and pulsed bump

135

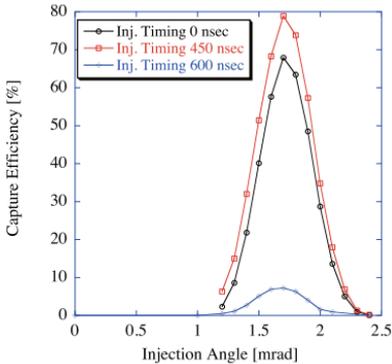

11

## Capture efficiency vs injection timing

12

## Capture efficiency vs injection angle

$$X = \frac{x}{\sqrt{\beta}}, \quad P = \frac{\alpha x + \beta \dot{x}}{\sqrt{\beta}}$$

$$\tan \varphi = \frac{P}{X}$$

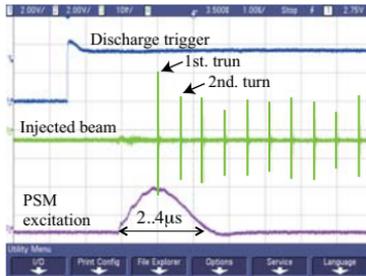

$$E_{\text{cap}} = \frac{\# \text{ of particles at } 100^{\text{th}} \text{ turn}}{\# \text{ of particles at } 1^{\text{st}} \text{ turn}}$$

136

13

## Timing tuning

RF power off

- Revolution period ~ 0.6 μsec
- Excitation pulse width of 1.2 μsec or less is preferable
- The existing pulsed power supply has the full width of 2.4 μsec

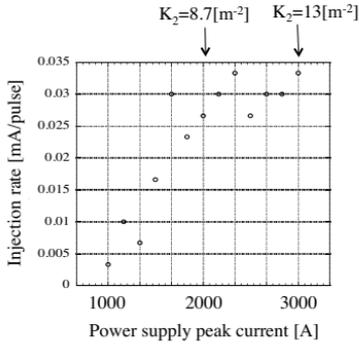

2nd. kick to injected beam

- Peak current is 3000A at 16.7kV
- WCM with 150MHz HPP

14

---

## Injection rate ( $K_2$ dependency)

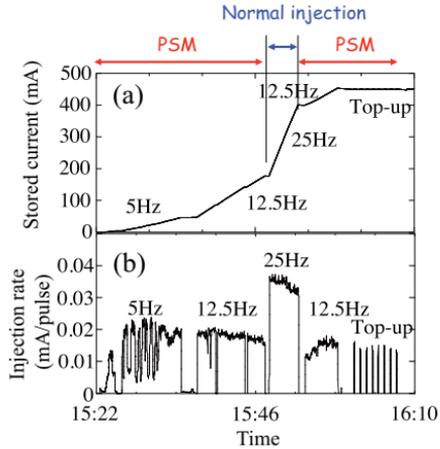

137

---

15

---

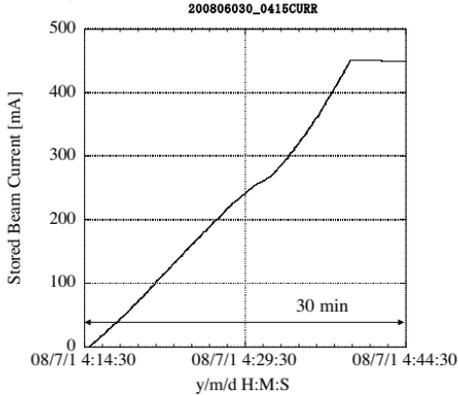

## Multi-bunch beam injection using the PSM

---

16

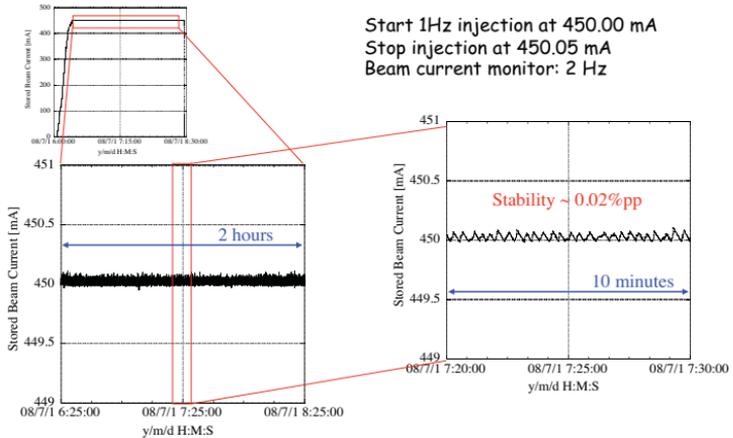

## Multi-bunch injection with PSM

Repetition frequency of 12.5 Hz  
We could store the beam up to the current of 450 mA

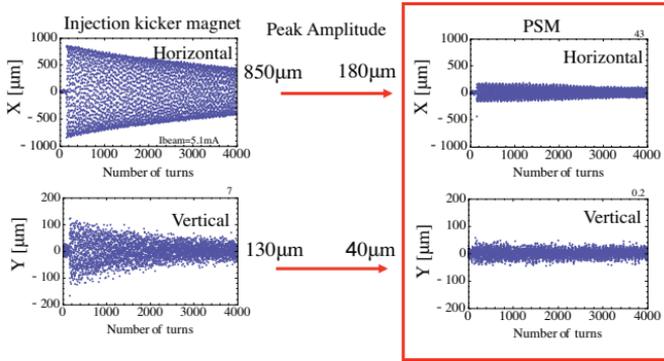

17

## Continuous (Top-up) beam injection with PSM

18

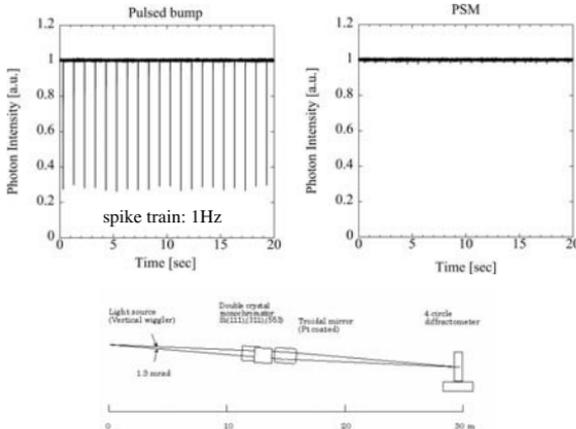

## Stored beam oscillation during beam injection

The dipole oscillations of the stored beam in the PSM injection were sufficiently reduced.

19

## BL-14A PIN photodiode output

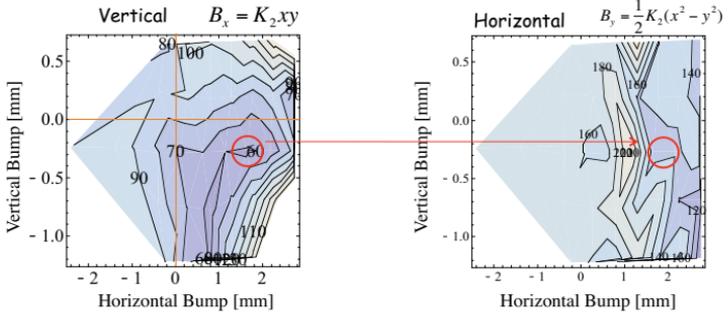

20

## Beam based field center search (preliminary)

Maximum vertical oscillation amplitude  
of the stored beam

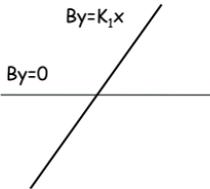

NOT decreasing horizontally

21

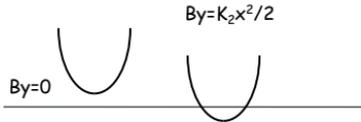

## Zero field point problem of the sextupole magnet

Quadrupole magnet

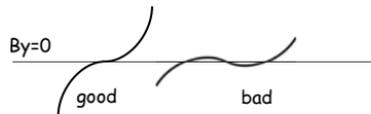

Q-mag has only one "zero point"  
somewhere

Sextupole magnet

NOT for a sextupole magnet or higher.

Octupole magnet

22

---

## Solutions

- (1) Pulsed dipole magnet for correction
  - 180  $\mu\text{m}$  needs 0.03 mrad kick ( $K_2=13 \text{ m}^{-2} \sim 1.5 \text{ mrad @ 15 mm}$ )
  - may produce mismatch of 2 magnets (discarding PSM policy)
- (2) Remote controllable end-shim to produce dipole field
- (3) Something else

---

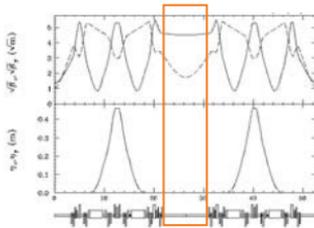

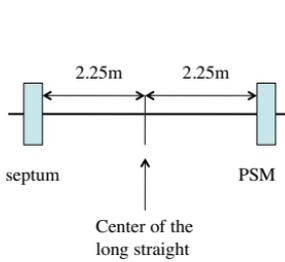

23

---

## NLSL-II injection parameters (single particle simulations)

- Injected beam is 25 mm off axis at the exit of injection septum
  - Septum magnet is 4.5 m away from PSM in the same straight.
  - The ring horizontal acceptance is +/- 15 mm in the center of the straight section, where  $\text{betax}=20\text{m}$ .
-

## Injection point

$x_0 = 25 \text{ mm}$  at the exit of the septum magnet

25

## $K_2$ (High-beta section)

$$W_{red} = \gamma x^2 + 2\alpha x x' + \beta x'^2 = 11.25 [\text{mm} \cdot \text{mrad}] \quad (x=15\text{mm}, x'=0, \beta=20\text{m}, \alpha=0)$$

$$L = 2.25 [\text{m}]$$

$$x_0 = 25 [\text{mm}]$$

$$W_{inj} = 123 [\text{mm} \cdot \text{mrad}]$$

$$L = 2.25 [\text{m}]$$

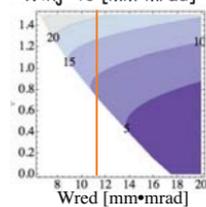

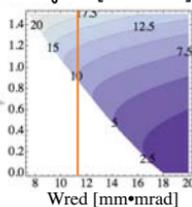

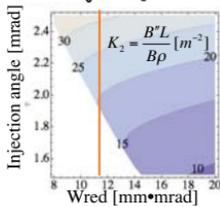

$$x_0 = 20 [\text{mm}]$$

$$W_{inj} = 40 [\text{mm} \cdot \text{mrad}]$$

$$L = 2.5 [\text{m}]$$

$$x_0 = 20 [\text{mm}]$$

$$W_{inj} = 40 [\text{mm} \cdot \text{mrad}]$$

Septum width + beam size, etc.

$$15 [\text{mm}] + \frac{\sqrt{20.5 (\text{septum})}}{\sqrt{20 (\text{center})}} + 5 [\text{mm}] \sim 20 [\text{mm}]$$

Physical aperture at the center of the straight section

---

## SUMMARY

- Experimental results
  - We successfully injected an electron beam with PSM.
  - Stored beam oscillation was smaller than that of the conventional injection system.
  - The PSM injection is suitable for "top-up injection".

## Summary: SLAC Kicker Technologies Applicable to NSLS-II Requirements

- Slow-sinusoidal kickers
  - A-line
    - 3.2 kG-m per 1-m magnet
    - 1.7 ms period
  - LCLS BX/BYKIK
    - 0.43 kG-m per 1-m magnet
    - 420  $\mu$ s period (BYKIK: 2 magnets, 400' cable)
- Fast-matched impedance kickers
  - SPEAR3
    - 3.1 kG-m per 1.2-m magnet
    - Solid state modulator
    - $T_R/T_F < 375$  ns (reduce with magnetic switching?),  $T < 750$  ns
  - SLC Damping Ring/ATF
    - 0.21 kG-m per 0.5-m magnet
    - $T_R/T_F \sim 30$  ns,  $T = 60$  ns (SLC), 300 ns (ATF)

# Field Measurements in Pulsed Magnets

---

166

Pulsed Magnet Design and Measurement Workshop  
July 27-28 2009

Animesh Jain, BNL

## Introduction

---

- Measurement techniques for field measurements in magnets operating at a DC field are well established.
  - *Rotating coils, Flip coils, Hall probes, NMR, ....*
- For time varying fields (AC or pulsed), several of the well established techniques can not be used.
- The most appropriate measurement method depends on the time scale of interest, and the field parameters that need to be measured.
- Some examples of AC and pulsed magnetic field measurements will be presented in this talk.

Disclosure: *Examples are drawn from personal experience only.*

# Some Measurement Techniques & Time Scales

Time Scale	Measurement Technique	Quantity Measured
DC	Rotating Coils	Main field and harmonics
	Sliding Coils/Flip Coils	Main field and field homogeneity
	Hall probes (1D/3D)	Local field (Component/Vector)
	Stretched Wire	Main field; Magnetic Center
	NMR (in uniform field only)	Field Magnitude
~ 1 s	Rotating Coils with special analysis	Main field and harmonics
	Hall probes (1D/3D)	Local field (Component/Vector)
> 100 ms	Fast Rotating Coils (Special Geometry)	Specific harmonics
	Hall probe arrays	Specific harmonics
	Hall probes (1D/3D)	Local field (Component/Vector)
> 1 ms	Stationary Coils (Special Geometry)	Main field
	Stationary Coil Array	Main field and harmonics
	Hall probe arrays	Specific harmonics
	Analog Hall probes (1D/3D)	Local field (Component/Vector)
< 1 ms	Stationary Coils (Special Geometry)	Main field
	Stationary Coil Array	Main field and harmonics

167

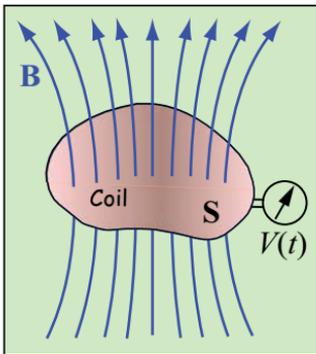

Pulsed Magnet Design and Measurement Workshop, July 27-28, 2009

2

## Pick up Coils: General Principle

Time dependence of flux gives:

$$V(t) = -\frac{d\Phi}{dt} = -\frac{d}{dt} \left[ \int_S \mathbf{B} \cdot d\mathbf{S} \right]$$

The change in flux is given by:

$$\Phi_{end} - \Phi_{start} = - \int_{t_{start}}^{t_{end}} V(t) \cdot dt$$

and can be measured by integrating the voltage signal.

To know the flux at a given instant, one needs to know  $\Phi_{start}$   
 $\Rightarrow$  (1) Use  $\Phi_{start} = 0$ ; (2) Flip Coil/Rotating coil:  $\Phi_{end} = -\Phi_{start}$

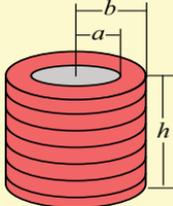

Pulsed Magnet Design and Measurement Workshop, July 27-28, 2009

3

# Some Coil Geometries

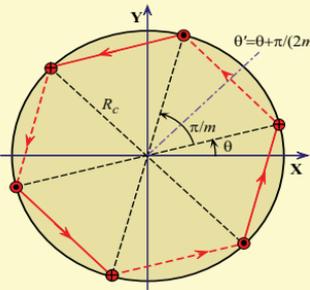

**Point Coil**  
 Insensitive up to 4<sup>th</sup> order spatial harmonics (octupole) with proper choice of height and radii.

$$h = \sqrt{\left(\frac{9}{5}\right) \left(\frac{b^5 - a^5}{b^3 - a^3}\right)}$$

**Flat Coil (Line or Area Coil)**

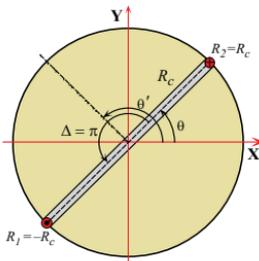

- Fixed coil, Varying field
- Flip Coil/Moving Coil, Static field
- Rotating Tangential/Radial Coils
- Can be made insensitive to higher order terms with special designs.

**Multipole Coil**  
 Sensitive to only odd multiples of a specified harmonic (Morgan Coils)

168

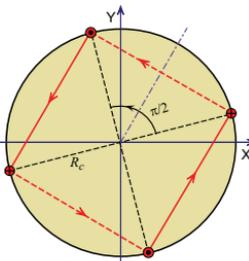

## Examples of Multipole Coils

**Dipole Coil**

- Single 180 deg. Loop
- Sensitive to  $n = 1, 3, \dots$

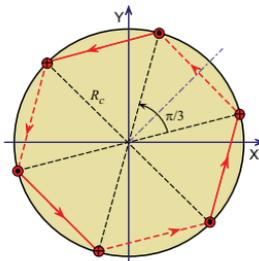

Sensitive to *all* terms if loop  $\neq 180/k$  ( $k = \text{integer}$ )

**Quadrupole Coil**

- Two 90 deg. Loops, 180 deg. apart, in series
- Sensitive to  $n = 2, 6, 10, \dots$

Sensitive to *all even* terms if loop  $\neq 90$  deg.

**Sextupole Coil**

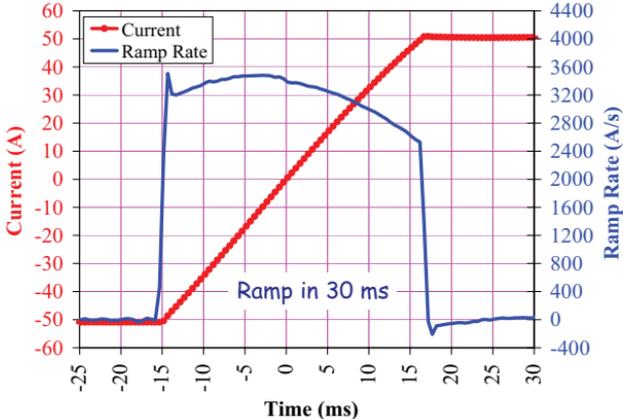

- Three 60 deg. Loops, 120 deg. apart, in series
- Sensitive to  $n = 3, 9, 15, \dots$

Sensitive to *all* multiples of  $n=3$  if loop  $\neq 60$  deg.

# Data Analysis

Power Supply Control Voltage:  $V(t) = V_0 \sin(2\pi ft)$

Current in Magnet:  $I(t) = I_0 \sin(2\pi ft - \alpha)$

Field in Magnet:  $B(t) = B_0 \sin(2\pi ft - \alpha - \varphi)$

Pickup Signal:  $S(t) \propto \frac{dB}{dt} = S_0 \cos(2\pi ft - \alpha - \varphi)$

$$\langle I(t) * I(t) \rangle = \frac{1}{2} I_0^2 ; \langle S(t) * S(t) \rangle = \frac{1}{2} S_0^2 ; \langle I(t) * S(t) \rangle = \frac{1}{2} I_0 S_0 \cdot \sin \varphi$$

**Phase Shift  
between  
Current and Field:**

$$\sin \varphi = \frac{\langle I(t) * S(t) \rangle}{\sqrt{\langle I(t) * I(t) \rangle \cdot \langle S(t) * S(t) \rangle}}$$

**Transfer Function:**

$$\frac{B_0}{I_0} \propto \left( \frac{1}{f} \right) \cdot \left[ \frac{\langle S(t) * S(t) \rangle}{\langle I(t) * I(t) \rangle} \right]^{1/2}$$

# Measurements Using an Array of Coils

- Sometimes it may not be enough to measure just the main field.
- In order to measure field homogeneity (equivalently, the field harmonics), it is necessary to measure the field at many points in space.
- Ideally, one needs an array of similar coils to measure field harmonics. The number of coils depends on the number of harmonics of interest.
- For precise measurement of harmonics, all coils in the array must be built as close to each other as possible, and inter-calibrated precisely.
- It may be possible to use fewer coils and several angular positions to effectively increase the array size, provided ramps are reproducible.

## Fast Tune Jump Quads in AGS

- Fast tune jump quadrupoles will be installed in the Alternating Gradient Synchrotron at BNL to overcome horizontal depolarizing resonances.
- The pulse profile is given by:
  - 100  $\mu$ s rise time (0 to 1 kA), 4 ms flat top, 100  $\mu$ s fall time (0 to 1 kA)
- Quadrupole field and some harmonics were measured using a coil with 3 different windings (D1, T1 and T2) in 72 orientations.
- D1 is a dipole winding (180 deg.) with 3 turns, and is sensitive to all odd harmonics.
- T1 and T2 are two tangential windings, 180 deg. apart, with  $\sim$ 14 deg. opening angle and a single turn.
- (T1+T2) contains all even terms, (T1-T2) contains all odd terms.

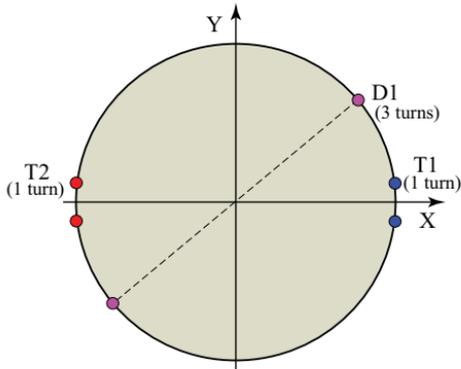

Pulsed Magnet Design and Measurement Workshop, July 27-28, 2009

21

# Measuring Coil for Fast Tune Jump Quads

An existing RHIC coil was modified for these measurements.

Measurements were made at 72 different coil orientations to get harmonics.

D1 is sensitive to odd harmonics only.

T1 and T2 are sensitive to all harmonics.

$(T1+T2)$  is predominantly sensitive to even terms only.

$(T1-T2)$  is predominantly sensitive to odd terms only.

Comparison of  $(T1-T2)$  and D1 gives an estimate of errors.

Data acquired using NI-6123 ADC at 500 kHz (2  $\mu$ s time resolution).

# Summary

---

- Field quality measurement techniques for DC fields are well established.
- Measurements of field quality in changing fields become increasingly more difficult as the time scales become shorter.
- Pick up coils are perhaps the most convenient means of characterizing pulsed fields on a test bench.
- The main field component is relatively easy to obtain, but the measurement of harmonics requires extra care in probe calibration and control of other experimental parameters.
- Field quality measurements at microsecond time scales, and shorter, remain quite challenging at present.

NSLII Pulsed Magnet Workshop

22

# Achieved System Capability

- Pulsed Power: > 1 Giga-Watts
- Maximum Voltage: 100 KV
- Maximum Current: > 20 kA / module
- Pulse Duration: ns, us, or ms
- Rise / Fall Time: ns, us, or ms
- Burst Repetition Rate: 2000 PPS (test only)
- Continuous Operation  
Repetition Rate: 60Hz

192

## Pulsed Power System Design

- Complete Pulsed Power System design, such as high voltage modulators, pulse transmission systems, trigger systems, auxiliary systems, diagnostic and instrumentation systems, PLC and PLD design and programming, grounding and shielding designs, etc.
- Analysis and simulations, system layout, modulator layout, mechanical packaging, customer components development, installation, commission, etc.
- Experienced with both thyratrons & solid state devices

# Design and Operation Experience

- High voltage modulators located inside accelerator tunnels or in service buildings, driving load magnets directly or through high voltage transmission cables
- Control and auxiliary system located remotely in service buildings
- Unattended operations since 1990

## SNS Extraction Kicker System by BNL

July 28, 2009

NSLSII Pulsed Magnet Workshop

26

## ORNL SNS Extraction Kicker System by BNL

- A giga-watt class pulsed power system
- A state-of-art continuous operation high repetition rate pulsed power system
- Under budget, within schedule, excellent system performance, total customer satisfaction
