Study of Injection Capture vs a change in $\dot{B}$ (Nov 20, 1973)
HERRERA & RALPH

A. Initial Conditions

- 1) $\dot{B}$ vs time is shown on Fig. (1)
- 2) Spreading beam shown in Fig. (2)
- 3) Lens current about 45 to 50 ma for 120 psec.
- 4) Machine was tuned for max. accelerated beam of 6.0×10^{12} p/p. Early monitor about 7.2×10^{12}

B. Experiment:

- 1) $\dot{B}$ vs time changed (Fig. (3))
- 2) Spreading beam shown in Fig. (4)
- 3) Machine was tuned for max accelerated beam of about 6.5×10^{12} p/p. Early monitor was 8.0×10^{12}

C. Comments:

- 1) It appears that running at a higher $\dot{B}$ at injection with the higher r.f. voltage we presently use results in a higher overall accelerated beam.
- 2) Additional experiments with increased and decreased $\dot{B}$ are required.
