Booster Double Harmonic Setup Notes

C.J. Gardner

February 17, 2015

1 Motivation and Setup Scenario

1. Reducing the peak beam current reduces the transverse space charge force, which reduces beam loss due to resonance excitation. This reduction can be achieved by flattening the RF bucket with a second RF harmonic [1, 2, 3].
2. Flattening the RF bucket also reduces the momentum spread of the beam, which reduces tune spread due to nonzero chromaticity and can reduce beam loss in regions of nonzero dispersion.
3. RF capture and acceleration of polarized protons (PP) is first set up in the single harmonic mode with RF harmonic $h = 1$. PP are adiabatically captured at injection with $hf = 841.166738$ kHz (which corresponds to 200 MeV kinetic energy) and then accelerated to 1362.77885 kHz (which corresponds to $G_p\gamma = 4.5$).
4. This is normally done with RF stations A3 and B3, but here we use stations A6 and E6, so that A3 and B3 (which have a greater frequency range) can be used to introduce the second harmonic for the double harmonic setup.
5. Once capture and acceleration have been set up in the single harmonic mode, the second harmonic system is brought on (with stations A3 and B3) and programmed to operate in concert with the single harmonic system.
6. The second harmonic system operates at harmonic $2h = 2$ with capture at $2hf = 1.682$ MHz and acceleration to 2.726 MHz.
7. The phase and amplitude of the second harmonic are programmed to produce a flattened RF bucket throughout the magnetic cycle.

2 Equations for Turn-by-Turn Motion

The turn-by-turn motion for the double harmonic setup is governed by the potential U , where [4]

$$\frac{\partial U}{\partial \phi} = -F(\phi + \phi_s) + F(\phi_s) \quad (1)$$

$$F(\theta) = A_1 \sin \theta - A_2 \sin(2\theta - 2\psi_0). \quad (2)$$

and

$$A_1 = \frac{eQV_1}{2\pi h}, \quad A_2 = \frac{eQV_2}{2\pi h}. \quad (3)$$

Here ϕ_s is the stable synchronous phase and ϕ is the deviation from ϕ_s .

ψ_0 is an adjustable phase offset.

e is the proton charge and eQ is the charge of the particle.

h is the RF harmonic number for the single harmonic setup.

V_1 and V_2 are adjustable amplitudes of the first and second harmonic voltages.

Thus we have

$$\frac{\partial U}{\partial \phi} = -A_1 \sin(\phi + \phi_s) + A_2 \sin(2\phi + 2\phi_s - 2\psi_0) + C \quad (4)$$

$$\frac{\partial^2 U}{\partial^2 \phi} = -A_1 \cos(\phi + \phi_s) + 2A_2 \cos(2\phi + 2\phi_s - 2\psi_0) \quad (5)$$

and

$$U(\phi) = A_1 \cos(\phi + \phi_s) - \frac{1}{2}A_2 \cos(2\phi + 2\phi_s - 2\psi_0) + C\phi + D \quad (6)$$

where

$$C = A_1 \sin \phi_s - A_2 \sin(2\phi_s - 2\psi_0) \quad (7)$$

and D is a constant independent of ϕ .

If we define

$$\psi = \phi + \phi_s \quad (8)$$

then the potential U expressed as a function of ψ is

$$U(\psi) = A_1 \cos \psi - \frac{1}{2}A_2 \cos(2\psi - 2\psi_0) + C(\psi - \phi_s) + D. \quad (9)$$

Choosing

$$D = C\phi_s \quad (10)$$

we then have

$$U(\psi) = A_1 \cos \psi - \frac{1}{2} A_2 \cos(2\psi - 2\psi_0) + C\psi \quad (11)$$

$$\frac{\partial U}{\partial \psi} = -A_1 \sin \psi + A_2 \sin(2\psi - 2\psi_0) + C \quad (12)$$

and

$$\frac{\partial^2 U}{\partial^2 \psi} = -A_1 \cos \psi + 2A_2 \cos(2\psi - 2\psi_0) \quad (13)$$

where

$$C = A_1 \sin \phi_s - A_2 \sin(2\phi_s - 2\psi_0). \quad (14)$$

The turn-by-turn equations of motion are [4]

$$t_{n+1} = t_n + \frac{2\pi}{\omega_n^s} \left(\frac{\omega_n^s - \omega_n}{\omega_n} \right) \quad (15)$$

$$e_{n+1} = e_n + eQ \{V(T_{n+1}^s + t_{n+1}) - V(T_{n+1}^s)\} \quad (16)$$

where

$$V(T_{n+1}^s + t_{n+1}) = \left(\frac{2\pi h}{eQ} \right) F(\phi_{n+1} + \phi_{n+1}^s) \quad (17)$$

$$V(T_{n+1}^s) = \left(\frac{2\pi h}{eQ} \right) F(\phi_{n+1}^s) \quad (18)$$

and

$$\phi_n = t_n h \omega_n^s, \quad \phi_{n+1} = t_{n+1} h \omega_{n+1}^s. \quad (19)$$

Here t_n and e_n are the time and energy deviations of a given particle (with respect to the arrival time and energy of the synchronous particle), and ω_n and ω_n^s are the angular frequencies of the particle and synchronous particle, respectively. In (17) and (18) the RF voltage V is defined as an explicit function of time. We also define

$$V(\phi_{n+1} + \phi_{n+1}^s) = \left(\frac{2\pi h}{eQ} \right) F(\phi_{n+1} + \phi_{n+1}^s) \quad (20)$$

and

$$V(\phi_{n+1}^s) = \left(\frac{2\pi h}{eQ} \right) F(\phi_{n+1}^s). \quad (21)$$

3 RF Voltage

As a function of phase, the RF voltage for the single harmonic setup is

$$V(\psi) = V_1 \sin \psi. \quad (22)$$

The synchronous phase ϕ_1 is given by

$$V_1 \sin \phi_1 = 2\pi R_s \rho_s \left(\frac{1}{c} \frac{dB}{dt} \right) \quad (23)$$

where R_s and ρ_s are the radius and radius-of-curvature of the orbit followed by the synchronous particle, and B is the programmed guide field.

For the double harmonic setup the RF voltage is

$$V(\psi) = V_1 \sin \psi - V_2 \sin(2\psi - 2\psi_0). \quad (24)$$

The synchronous phase ϕ_s for this setup must satisfy

$$V(\phi_s) = V_1 \sin \phi_1 \quad (25)$$

where $V_1 \sin \phi_1$ is given by (23). Thus we must have

$$V_1 \sin \phi_s - V_2 \sin(2\phi_s - 2\psi_0) = V_1 \sin \phi_1. \quad (26)$$

Using a prime to denote differentiation with respect to ψ we have

$$V'(\phi_s) = V_1 \cos \phi_s - 2V_2 \cos(2\phi_s - 2\psi_0) \quad (27)$$

and

$$V''(\phi_s) = -V_1 \sin \phi_s + 4V_2 \sin(2\phi_s - 2\psi_0). \quad (28)$$

If we specify that

$$V'(\phi_s) = V_1 F, \quad V''(\phi_s) = V_1 G \quad (29)$$

for some F and G , then

$$V_1 \cos \phi_s - 2V_2 \cos(2\phi_s - 2\psi_0) = V_1 F \quad (30)$$

and

$$-V_1 \sin \phi_s + 4V_2 \sin(2\phi_s - 2\psi_0) = V_1 G. \quad (31)$$

Equations (26) and (31) can be written in matrix form as

$$\begin{pmatrix} V_1 & -V_2 \\ -V_1 & 4V_2 \end{pmatrix} \begin{pmatrix} \sin \phi_s \\ \sin(2\phi_s - 2\psi_0) \end{pmatrix} = \begin{pmatrix} V_1 \sin \phi_1 \\ V_1 G \end{pmatrix} \quad (32)$$

from which we obtain

$$3V_1V_2 \begin{pmatrix} \sin \phi_s \\ \sin(2\phi_s - 2\psi_0) \end{pmatrix} = \begin{pmatrix} 4V_2 & V_2 \\ V_1 & V_1 \end{pmatrix} \begin{pmatrix} V_1 \sin \phi_1 \\ V_1 G \end{pmatrix}. \quad (33)$$

Thus

$$3 \sin \phi_s = 4 \sin \phi_1 + G \quad (34)$$

and

$$3V_2 \sin(2\phi_s - 2\psi_0) = V_1 (\sin \phi_1 + G). \quad (35)$$

From (30) we also have

$$2V_2 \cos(2\phi_s - 2\psi_0) = V_1 (\cos \phi_s - F). \quad (36)$$

Dividing (35) by (36) then gives

$$\tan(2\phi_s - 2\psi_0) = \frac{2}{3} \left(\frac{\sin \phi_1 + G}{\cos \phi_s - F} \right). \quad (37)$$

If ϕ_1 and G are given then ϕ_s can be obtained from equation (34). If F is also given then equation (37) gives ψ_0 and equation (36) gives

$$2V_2 = \frac{V_1 (\cos \phi_s - F)}{\cos(2\phi_s - 2\psi_0)}. \quad (38)$$

Thus if we specify the synchronous phase ϕ_1 for the single harmonic setup and if we choose values for the parameters F and G , then equations (34), (37), and (38) give the synchronous phase ϕ_s , the phase ψ_0 , and the ratio V_2/V_1 for the double harmonic setup.

4 Normalized Voltage, Potential, and RF Bucket

We define normalized voltage

$$\mathcal{V}(\psi) = \frac{1}{V_1} V(\psi) \quad (39)$$

and normalized potential

$$\mathcal{U}(\psi) = \frac{1}{A_1} \{U(\psi_u) - U(\psi)\} \quad (40)$$

where

$$V(\psi) = V_1 \sin \psi - V_2 \sin(2\psi - 2\psi_0) \quad (41)$$

$$U(\psi) = A_1 \cos \psi - \frac{1}{2} A_2 \cos(2\psi - 2\psi_0) + C\psi \quad (42)$$

and

$$C = A_1 \sin \phi_s - A_2 \sin(2\phi_s - 2\psi_0). \quad (43)$$

The normalized RF bucket is defined by the curves

$$\mathcal{B}(\psi) = \pm \sqrt{-\mathcal{U}(\psi)}. \quad (44)$$

The phase ψ_u appearing in (40) is the unstable synchronous phase defined by

$$V(\psi_u) = V(\phi_s) \quad (45)$$

and (below transition)

$$V'(\psi_u) < 0. \quad (46)$$

We then have

$$\mathcal{U}' = -\frac{1}{A_1} U'(\psi) \quad (47)$$

where

$$U'(\psi) = -A_1 \sin \psi + A_2 \sin(2\psi - 2\psi_0) + C \quad (48)$$

$$\begin{aligned} -\frac{1}{A_1} U'(\psi) &= \sin \psi - \frac{A_2}{A_1} \sin(2\psi - 2\psi_0) \\ &- \sin \phi_s + \frac{A_2}{A_1} \sin(2\phi_s - 2\psi_0). \end{aligned} \quad (49)$$

With the help of (3) we have

$$\frac{A_2}{A_1} = \frac{V_2}{V_1} \quad (50)$$

which gives

$$-\frac{1}{A_1} U'(\psi) = \frac{1}{V_1} V(\psi) - \frac{1}{V_1} V(\phi_s) \quad (51)$$

and

$$\mathcal{U}'(\psi) = \mathcal{V}(\psi) - \mathcal{V}(\phi_s). \quad (52)$$

Thus

$$\mathcal{U}''(\psi) = \mathcal{V}'(\psi), \quad \mathcal{U}'''(\psi) = \mathcal{V}''(\psi), \quad \mathcal{U}''''(\psi) = \mathcal{V}'''(\psi) \quad (53)$$

where

$$\mathcal{V}(\psi) = \sin \psi - \frac{V_2}{V_1} \sin(2\psi - 2\psi_0) \quad (54)$$

$$\mathcal{V}'(\psi) = \cos \psi - \frac{2V_2}{V_1} \cos(2\psi - 2\psi_0) \quad (55)$$

$$\mathcal{V}''(\psi) = -\sin \psi + \frac{4V_2}{V_1} \sin(2\psi - 2\psi_0) \quad (56)$$

$$\mathcal{V}'''(\psi) = -\cos \psi + \frac{8V_2}{V_1} \cos(2\psi - 2\psi_0). \quad (57)$$

Equations (55) and (57) also give

$$\mathcal{V}'''(\psi) + 4\mathcal{V}'(\psi) = 3\cos \psi. \quad (58)$$

Thus at the stable synchronous phase ϕ_s we have

$$\mathcal{V}(\phi_s) = \sin \phi_1, \quad \mathcal{V}'(\phi_s) = F, \quad \mathcal{V}''(\phi_s) = G \quad (59)$$

$$\mathcal{U}'(\phi_s) = 0, \quad \mathcal{U}''(\phi_s) = F, \quad \mathcal{U}'''(\phi_s) = G \quad (60)$$

and

$$\mathcal{U}''''(\phi_s) = 3\cos \phi_s - 4F. \quad (61)$$

At the unstable synchronous phase we have

$$\mathcal{V}(\psi_u) = \mathcal{V}(\phi_s), \quad \mathcal{U}(\psi_u) = 0, \quad \mathcal{U}'(\psi_u) = 0. \quad (62)$$

Expanding the normalized potential about the stable synchronous phase we have

$$\begin{aligned} \mathcal{U}(\psi) &= \mathcal{U}(\phi_s) + \frac{1}{2!} F(\psi - \phi_s)^2 + \frac{1}{3!} G(\psi - \phi_s)^3 \\ &+ \frac{1}{4!} (3\cos \phi_s - 4F) (\psi - \phi_s)^4 + \dots \end{aligned} \quad (63)$$

If $F > 0$ then $\mathcal{U}(\psi)$ reaches a minimum at $\psi = \phi_s$. We can make the minimum flat by keeping F small and positive. This produces a flattened RF bucket. Note that if G is nonzero then the minimum will not be centered in the potential well.

If $F = 0$ and $G = 0$ then

$$\mathcal{U}(\psi) = \mathcal{U}(\phi_s) + \frac{1}{4!} (3\cos \phi_s) (\psi - \phi_s)^4 + \dots \quad (64)$$

which also gives a flat minimum at $\psi = \phi_s$. In this case the minimum is centered in the potential well.

5 Flattened Bucket Option I

Suppose we want to keep the synchronous phase the same for the single and double harmonic setups. This means that the second harmonic voltage must be zero at the synchronous phase ϕ_1 for the single harmonic setup. The RF system can then use the calculated value of ϕ_1 to set the phase ψ_0 of the second harmonic voltage.

For easy reference we write down equations (34), (37), and (38) here as

$$3 \sin \phi_s = 4 \sin \phi_1 + G \quad (65)$$

$$\tan(2\phi_s - 2\psi_0) = \frac{2}{3} \left(\frac{\sin \phi_1 + G}{\cos \phi_s - F} \right) \quad (66)$$

$$2V_2 \cos(2\phi_s - 2\psi_0) = V_1(\cos \phi_s - F). \quad (67)$$

Then we have

$$\phi_s = \phi_1 \quad (68)$$

and it follows from (65), (66), and (67) that

$$G = -\sin \phi_1, \quad \psi_0 = \phi_s = \phi_1, \quad 2V_2 = V_1(\cos \phi_s - F). \quad (69)$$

For a flattened RF bucket we want F to be small and positive. This gives

$$2V_2 < V_1 \cos \phi_s \quad (70)$$

with $2V_2$ close to but less than $V_1 \cos \phi_s$. We call this Flattened Bucket Option I.

If we take single harmonic stable synchronous phase

$$\phi_1 = 30^\circ \quad (71)$$

then we have

$$\phi_s = 30^\circ, \quad \psi_0 = 30^\circ, \quad \frac{V_2}{V_1} < 0.4330127. \quad (72)$$

Figure 1 shows the normalized potential and RF bucket for the case in which $V_2/V_1 = 0.41$.

Figure 2 is a magnified view of **Figure 1** showing that the normalized potential does indeed reach a minimum at $\phi_s = 30^\circ$. Note that the minimum is not centered in the potential well.

6 Flattened Bucket Option II

If we want a flattened bucket with

$$V'(\phi_s) = 0, \quad V''(\phi_s) = 0 \quad (73)$$

then we have

$$F = 0, \quad G = 0 \quad (74)$$

and it follows from (65), (66), and (67) that

$$\sin \phi_s = \frac{4}{3} \sin \phi_1, \quad \sin \phi_1 = \frac{3}{4} \sin \phi_s \quad (75)$$

$$\tan(2\phi_s - 2\psi_0) = \frac{1}{2} \tan \phi_s \quad (76)$$

and

$$2V_2 = \frac{V_1 \cos \phi_s}{\cos(2\phi_s - 2\psi_0)}. \quad (77)$$

These equations give

$$\phi_s = \arcsin \left\{ \frac{4}{3} \sin \phi_1 \right\} \quad (78)$$

$$\psi_0 = \phi_s - \frac{1}{2} \arctan \left\{ \frac{1}{2} \tan \phi_s \right\} \quad (79)$$

and

$$\frac{V_2}{V_1} = \frac{\cos \phi_s}{2 \cos(2\phi_s - 2\psi_0)}. \quad (80)$$

We call this Flattened Bucket Option II.

If we again take single harmonic stable synchronous phase

$$\phi_1 = 30^\circ \quad (81)$$

then we have

$$\phi_s = 41.8103^\circ, \quad \psi_0 = 29.7629^\circ, \quad V_2/V_1 = 0.408248. \quad (82)$$

Note that the value of ψ_0 obtained here is very close to the value obtained in the previous section for Flattened Bucket Option I.

Figure 3 shows the normalized potential and RF bucket for these numbers. **Figure 4** is a magnified view of **Figure 3** showing that the normalized potential does indeed reach a minimum at $\phi_s = 41.8103^\circ$. Note that the minimum is now centered in the potential well.

Figure 5 shows the potential wells of **Figures 2** and **4** together for comparison. The stable synchronous phases are 30° and 41.8103° , respectively. Although these are different, the centers of the two wells are very nearly the same.

7 RF Capture

During injection of PP in Booster the guide field is held constant and RF capture takes place by raising the RF voltage adiabatically from zero.

For capture with the single harmonic setup the stable synchronous phase is

$$\phi_1 = 0. \quad (83)$$

Figure 6 shows the normalized voltage, potential, and RF bucket. Here

$$\mathcal{V}(\psi) = \sin \psi \quad (84)$$

and

$$\mathcal{U}(\psi) = -\cos \psi - 1. \quad (85)$$

For capture with the double harmonic setup we take

$$\phi_s = \phi_1 = 0. \quad (86)$$

Equations (65), (66), and (67) then give

$$G = 0, \quad \psi_0 = 0, \quad 2V_2 = V_1(1 - F). \quad (87)$$

Taking $F = 0$ then gives the conditions for Flattened Bucket Option II.

Figure 7 shows the normalized harmonic 1 and 2 voltages and their sum

$$\mathcal{V}(\psi) = \sin \psi - \frac{V_2}{V_1} \sin 2\psi. \quad (88)$$

Here

$$V_2/V_1 = 1/2 \quad (89)$$

$$\mathcal{V}(\phi_s) = 0, \quad \mathcal{V}'(\phi_s) = 0, \quad \mathcal{V}''(\phi_s) = 0, \quad \mathcal{V}'''(\phi_s) = 3 \quad (90)$$

$$\mathcal{U}'(\phi_s) = 0, \quad \mathcal{U}''(\phi_s) = 0, \quad \mathcal{U}'''(\phi_s) = 0, \quad \mathcal{U}''''(\phi_s) = 3 \quad (91)$$

and

$$\mathcal{U}(\psi) = \mathcal{U}(0) + \frac{3}{4!} \psi^4 + \dots \quad (92)$$

Figures 8 and 9 show the normalized potential and RF bucket.

Figures 10 and 11 show the normalized voltages, potentials, and RF buckets for single and double harmonic capture together for comparison.

Figure 12 shows the result of simulated single harmonic capture of PP in Booster at injection. The simulation starts with a uniform distribution of unbunched beam consisting of a 100-by-100 array of particles covering the rectangle indicated in the figure. The area of the distribution is 1 eV s. The kinetic energy of the synchronous particle at the center of the distribution is 200 MeV. The RF voltage amplitude V_1 is raised quadratically from zero to 2 kV over a time interval of 8 ms.

Figure 13 shows the result of simulated double harmonic capture of PP at injection. The simulation starts with the same uniform distribution of unbunched beam as before. The RF voltage amplitude V_1 is again raised quadratically from zero to 2 kV over a time interval of 8 ms, but now the second harmonic voltage follows along with amplitude $V_2 = V_1/2$.

Figure 14 shows the two simulation results together for comparison. The bunch obtained with double harmonic capture is noticeably flatter. This effect becomes much more pronounced with acceleration.

8 Acceleration

During acceleration of PP in Booster with the single harmonic setup, the stable synchronous phase increases from zero at capture to a maximum of

$$\phi_1 = 30^\circ. \quad (93)$$

For Flattened Bucket Option I with $\phi_1 = 30$ degrees we have

$$\phi_s = 30^\circ, \quad \psi_0 = 30^\circ, \quad V_2/V_1 < 0.4330127 \quad (94)$$

and for Flattened Bucket Option II

$$\phi_s = 41.8103^\circ, \quad \psi_0 = 29.7629^\circ, \quad V_2/V_1 = 0.408248. \quad (95)$$

Figure 15 shows the normalized voltage, potential, and RF bucket for single harmonic acceleration of PP in Booster with stable synchronous phase $\phi_1 = 30^\circ$.

Figures 16, 17, and 18 show the normalized voltages, potential, and RF bucket for double harmonic acceleration of PP in Booster with Flattened Bucket Option I. Here $\phi_s = \phi_1 = 30^\circ$, $\psi_0 = 30^\circ$, and $V_2/V_1 = 0.41$, just as in **Figures 1 and 2**.

Figures 19 and 20 show the normalized voltages, potentials, and RF buckets of **Figures 15 and 18** together for comparison. One can see by inspection that for a stable synchronous phase of 30 degrees, the double harmonic bucket area is **larger** than that of the single harmonic bucket.

Figure 21 gives the same comparison for a stable synchronous phase of 35 degrees. For the double harmonic setup, Flattened Bucket Option I has been used with $\phi_s = \phi_1 = 35^\circ$, $\psi_0 = 35^\circ$, and $V_2/V_1 = 0.384$. One can see by inspection that the double harmonic bucket area is **slightly smaller** than that of the single harmonic bucket.

Figure 22 gives the comparison for a stable synchronous phase of 40 degrees. For the double harmonic setup, Flattened Bucket Option I has been used with $\phi_s = \phi_1 = 40^\circ$, $\psi_0 = 40^\circ$, and $V_2/V_1 = 0.347$. One can see by inspection that the double harmonic bucket area is **significantly smaller** than that of the single harmonic bucket. Thus for synchronous phases greater than 35 degrees, the double harmonic setup may not be particularly useful.

Figure 23 shows the result of simulated single harmonic acceleration of PP in Booster. Here a 1 eV s uniform distribution of unbunched beam was captured as in **Figure 12** and then accelerated to a synchronous proton kinetic energy of 386.8495 MeV. The corresponding revolution frequency is 1.04915084266 MHz. The stable synchronous phase is 30 degrees.

Figure 24 shows the result of simulated double harmonic acceleration using Flattened Bucket Option I. Here a 1 eV s uniform distribution of unbunched beam was captured as in **Figure 13** and again accelerated to a synchronous proton kinetic energy of 386.8495 MeV. The stable synchronous phase is again 30 degrees. Note that the bucket and bunch are not centered on the synchronous phase (which has time deviation zero in the figure), but the bunch is centered in the bucket. This is in accordance with **Figure 5** and the findings of sections 5 and 6.

Figure 25 shows the simulation results of **Figures 23 and 24** together for comparison.

Figure 26 shows the binned data of **Figure 25**. Here one sees that the double harmonic setup reduces the peak current by about 30%.

Figure 27 gives a comparison of the results of simulated single and double harmonic acceleration, but now with Flattened Bucket Option II used for the double harmonic setup. The synchronous proton kinetic energy is again 386.8495 MeV. The stable synchronous phase for the double harmonic setup is 41.8103 degrees. Note that the flattened bucket and bunch are now centered on the synchronous phase (which has time deviation zero in the figure). This is again in accordance with **Figure 5** and the findings of sections 5 and 6.

Figure 28 shows the binned data of **Figure 27**. Here again one sees that the double harmonic setup reduces the peak current by about 30%.

9 Implementation

The Booster RF system was set up as outlined in section 1. Flattened Bucket Option I was adopted as the simplest way to move from the single to the double harmonic setup. Freddy Severino [5] and Kevin Smith made the necessary changes to the RF system. In particular, they used the calculated synchronous phase ϕ_1 for the single harmonic setup to automatically set the phase ψ_0 of the second harmonic voltage. With the help of a mountain range display of the circulating bunched beam, the amplitude V_2 was then programmed by Keith Zeno to produce flattened bunches. The end result was significantly reduced beam loss during early acceleration where the space charge force is largest [6, 7, 8, 9]. The double harmonic setup has been found to be robust in that once it has been set up, it requires minimal further tuning.

In the future we may want to consider using Flattened Bucket Option II. This would allow the second harmonic voltage V_2 to be programmed automatically. From the synchronous phase ϕ_1 of the single harmonic setup one would use equations (78), (79), and (80) to calculate ϕ_s , ψ_0 , and V_2 .

Figures 29 and **30** show the values of ϕ_s , ψ_0 , and V_2/V_1 obtained as ϕ_1 varies from 0 to 30 degrees.

Figure 31 shows ϕ_1 , ϕ_s , ψ_0 , and V_2/V_1 along with the guide field B and dB/dt for capture of PP at 200 MeV and acceleration to 386.8495 MeV (kinetic energy) using Flattened Bucket Option II.

Figure 1: Normalized potential (blue curve) and RF bucket (green curve) for Flattened Bucket Option I. Here $\phi_s = \phi_1 = 30^\circ$, $\psi_0 = 30^\circ$, and $V_2/V_2 = 0.41$. The dashed blue line marks the stable synchronous phase ϕ_s .

Figure 2: Magnified view of **Figure 1** showing that the normalized potential for Flattened Bucket Option I does indeed reach a minimum at $\phi_s = 30^\circ$. Note that the minimum is not centered in the potential well.

Figure 3: Normalized potential (blue curve) and RF bucket (green curve) for Flattened Bucket Option II. Here $\phi_s = 41.8103^\circ$, $\psi_0 = 29.7629^\circ$, and $V_2/V_1 = 0.408248$. The dashed blue line marks the stable synchronous phase ϕ_s .

Figure 4: Magnified view of **Figure 3** showing that the normalized potential for Flattened Bucket Option II does indeed reach a minimum at $\phi_s = 41.8103^\circ$. Note that the minimum is now centered in the potential well.

Figure 5: Here the potential wells of **Figures 2** and **4** are shown together for comparison. The corresponding stable synchronous phases are 30° and 41.8103° , respectively. Although these are different, the centers of the two wells are very nearly the same.

Figure 6: Normalized voltage, potential, and RF bucket for single harmonic capture of PP at Booster injection. These are the orange, blue, and green curves respectively. The horizontal axis gives the phase ψ in degrees. The voltage $V(\psi) = V_1 \sin \psi$ goes from negative to positive as ψ passes through the stable synchronous phase $\phi_1 = 0$. The normalized potential is $\mathcal{U}(\psi) = -\cos \psi - 1$.

Figure 7: Normalized harmonic 1 and 2 voltages and their sum for double harmonic capture of PP at Booster injection. These are the black, brown, and orange curves, respectively. The horizontal axis gives the phase ψ in degrees. The sum of the voltages is $V(\psi) = V_1 \sin \psi - V_2 \sin 2\psi$. Note that the harmonic 2 voltage (brown curve) goes from positive to negative as the phase ψ passes through the stable synchronous phase $\phi_s = 0$. The ratio $V_2/V_1 = 1/2$ flattens the voltage sum at $\psi = \phi_s$.

Figure 8: Normalized voltages and potential for double harmonic capture of PP at Booster injection. The horizontal axis gives the phase ψ in degrees. The blue curve is the normalized potential. Its expansion about $\phi_s = 0$ is given by (92).

Figure 9: Normalized voltage, potential, and RF bucket for double harmonic capture of PP at Booster injection. The green curve is the RF bucket.

Figure 10: Here the normalized voltages, potentials, and RF buckets for single and double harmonic capture are shown together for comparison.

Figure 11: Same as **Figure 10** but showing just the normalized voltages and RF buckets.

Figure 12: Result of simulated single harmonic capture of PP in Booster at injection. The simulation starts with a uniform distribution of unbunched beam consisting of a 100-by-100 array of particles covering the rectangle indicated in the figure. The area of the distribution is 1 eV s. The kinetic energy of the synchronous particle at the center of the distribution is 200 MeV. The RF voltage amplitude V_1 is raised quadratically from zero to 2 kV over a time interval of 8 ms. The units of the horizontal and vertical axes are nanoseconds and MeV respectively. The synchronous revolution period is 1188.825 nanoseconds.

Figure 13: Result of simulated double harmonic capture of PP at injection. The simulation starts with the same uniform distribution of unbunched beam as before. The RF voltage amplitude V_1 is again raised quadratically from zero to 2 kV over a time interval of 8 ms, but now the second harmonic voltage follows along with amplitude $V_2 = V_1/2$. The units of the horizontal and vertical axes are again nanoseconds and MeV. The synchronous revolution period is 1188.825 nanoseconds.

Figure 14: Here the results of simulated single and double harmonic capture of PP in Booster are shown together for comparison. The bunch obtained with double harmonic capture is noticeably flatter. This effect becomes much more pronounced with acceleration.

Figure 15: Normalized voltage, potential, and RF bucket for single harmonic acceleration in Booster. These are the orange, blue, and green curves respectively. The stable synchronous phase is 30 degrees. The stable and unstable synchronous phases are marked by the dashed vertical lines at 30 and 150 degrees respectively.

Figure 16: Normalized harmonic 1 and 2 voltages and their sum $\mathcal{V}(\psi) = \sin \psi - (V_2/V_1) \sin(2\psi - 2\phi_s)$ for double harmonic acceleration in Booster. These are the black, brown, and orange curves, respectively. The stable and unstable synchronous phases are marked by the dashed vertical lines at 30 and 173.745 degrees respectively. Here we have used Flattened Bucket Option I with $\phi_s = \phi_1 = 30^\circ$, $\psi_0 = 30^\circ$, and $V_2/V_1 = 0.41$, just as in **Figures 1** and **2**. Note that the harmonic 2 voltage (brown curve) goes from positive to negative and the sum of the voltages is flattened as the phase ψ passes through the stable synchronous phase.

Figure 17: Same as **Figure 16** but showing the normalized potential (blue curve). A magnified view of this potential is shown in **Figure 2**.

Figure 18: Same as **Figure 17** but showing the RF bucket (green curve).

Figure 19: Here the normalized voltages, potentials, and RF buckets of **Figures 15** and **18** are shown together for comparison.

Figure 20: Same as **Figure 19** but showing just the normalized voltages and RF buckets. One can see by inspection that for a stable synchronous phase of 30 degrees, the double harmonic bucket area is **larger** than that of the single harmonic bucket.

Figure 21: Same comparison but with a stable synchronous phase of 35 degrees. For the double harmonic setup, Flattened Bucket Option I has been used with $\phi_s = \phi_1 = 35^\circ$, $\psi_0 = 35^\circ$, and $V_2/V_1 = 0.384$. One can see by inspection that the double harmonic bucket area is **slightly smaller** than that of the single harmonic bucket.

Figure 22: Same comparison but with a stable synchronous phase of 40 degrees. For the double harmonic setup, Flattened Bucket Option I has been used with $\phi_s = \phi_1 = 40^\circ$, $\psi_0 = 40^\circ$, and $V_2/V_1 = 0.347$. One can see by inspection that the double harmonic bucket area is **significantly smaller** than that of the single harmonic bucket.

Figure 23: Result of simulated single harmonic acceleration of PP in Booster. Here a 1 eVs uniform distribution of unbunched beam was captured as in **Figure 12** and then accelerated to a synchronous proton kinetic energy of 386.8495 MeV. The corresponding revolution frequency is 1.04915084266 MHz. The stable synchronous phase is 30 degrees. The units of the horizontal and vertical axes are nanoseconds and MeV respectively. The synchronous revolution period is 953.1518 nanoseconds.

Figure 24: Result of simulated double harmonic acceleration of PP in Booster using Flattened Bucket Option I. Here a 1 eV s uniform distribution of unbunched beam was captured as in **Figure 13** and again accelerated to a synchronous proton kinetic energy of 386.8495 MeV. The stable synchronous phase is again 30 degrees. Note that the bucket and bunch are not centered on the synchronous phase (which has time deviation zero in the figure), but the bunch is centered in the bucket. This is in accordance with **Figure 5** and the findings of sections 5 and 6. The units of the horizontal and vertical axes are nanoseconds and MeV respectively. The synchronous revolution period is 953.1518 nanoseconds.

Figure 25: Here the simulation results of **Figures 23** and **24** are shown together for comparison. The units of the horizontal and vertical axes are nanoseconds and MeV respectively. The synchronous revolution period is 953.1518 nanoseconds.

Figure 26: Binned data of **Figure 25** showing that the double harmonic setup reduces the peak current by about 30%. Here the horizontal axis gives the phase ψ in degrees.

Figure 27: Comparison of the results of simulated single and double harmonic acceleration, but now with Flattened Bucket Option II used for the double harmonic setup. The synchronous proton kinetic energy is again 386.8495 MeV. The stable synchronous phase for the double harmonic setup is 41.8103 degrees. Note that the flattened bucket and bunch are now centered on the synchronous phase (which has time deviation zero in the figure). This is again in accordance with **Figure 5** and the findings of sections 5 and 6. The units of the horizontal and vertical axes are nanoseconds and MeV respectively. The synchronous revolution period is 953.1518 nanoseconds.

Figure 28: Binned data of **Figure 27** showing again that the double harmonic setup reduces the peak current by about 30%. The horizontal axis gives the phase ψ in degrees.

Figure 29: ϕ_s (black curve) and ψ_0 (red curve) obtained as functions of ϕ_1 from (78) and (79) for Flattened Bucket Option II. Both axes are marked in degrees. The horizontal axis is ϕ_1 .

Figure 30: V_2/V_1 obtained from (78), (79), and (80) as a function of ϕ_1 for Flattened Bucket Option II. The horizontal axis is ϕ_1 marked in degrees.

Figure 31: Phases ϕ_1 , ϕ_s , ψ_0 , and ratio V_2/V_1 along with the guide field B and dB/dt for capture of PP at 200 MeV and acceleration to 386.8495 MeV (kinetic energy) using Flattened Bucket Option II. The horizontal axis is marked in ms from injection.
