1. Introduction

LEReC cooling section (CS) consists of two 20 m long parts (Fig. 1) each containing 6 solenoids with weak trajectory correctors placed inside the solenoids and the BPMs located downstream of each solenoid. The distance between solenoid centers is 3 m. The solenoids are used to minimize the scalloping of the electron beam envelope.

Figure 1: Schematic of LEReC cooling section.

We envision the following basic steps for the LEReC CS commissioning and demonstration of the cooling:

0. Prerequisites: electron beam energy and energy spread are optimized, cooling section is properly shielded.
1. Aligning CS BPMs with respect to the ion beam.
2. Aligning the trajectory of low charge electron beam by zeroing the e-beam displacement in each BPM. For properly shielded cooling section this step automatically guarantees [1] that electron beam trajectory angles throughout most of the CS are below 100 urad.
3. Performing beam-based alignment of the CS solenoids.
4. Setting proper focusing for high-charge e-beam in the CS.
5. Combining high-charge e-beam with low charge ion bunches in the cooling section. The charge of ions shall be low enough to have a negligible effect on e-beam focusing. We expect to observe cooling of the low charge ion beam at this step.
6. Increase ion charge and adjust the CS solenoids focusing respectively to obtain ions cooling with design parameters.

To obtain the cooling it is required to keep the overall RMS electron angles in the cooling section below 100 urad. Possible mechanical misalignment, such as shift and inclination (see Fig. 2), of the CS solenoids can cause an unacceptable misalignment of the e-beam trajectory

with respect to the ideal trajectory set by ions. Therefore, it is critical to go through step 3 in the procedure outlined above.

Figure 2: A solenoid magnetic center is shifted by d_x from and the solenoid is inclined by an angle α_x with respect to the optimal electron trajectory.

In this paper we will briefly describe step 1 of the procedure. Step 2 is trivial (for the properly shielded CS) and is covered by [1]. Most of our discussions will be devoted to step 3 of the procedure. Steps 4 and especially 6 require a separate study and will be covered in a future publication.

2. CS BPM alignment

The electron beam consists of macro-bunches repeated with 9 MHz frequency, which coincides with the frequency of stored ion bunches traveling through the cooling section. Each macro-bunch of electron consists of 30 bunches repeated with the frequency of 704 MHz.

We suggest the following general algorithm for the alignment of the CS BPMs:

1. Send the e-beam with desired current through the CS and observe the intensity of the CS BPM signals with 9 MHz band pass filter.
2. Stop the electron beam and inject the ion beam of such current that the CS BPM signals have the same intensity that they did for the e-beam.
3. Set the desired ion trajectory through the cooling section using well-calibrated existing RHIC BPMs and centering the ion beam in the nearby RHIC quads.
4. Measure the positions of the ions in the CS BPMs with 9 MHz band pass filter. We will call these positions BPM_{9i0} .
5. "Turn off" ions, "turn on" electrons and measure electron beam positions in the CS BPMs using 9 MHz filter. We call these positions BPM_{9e0} .
6. Switch to 704 MHz filter, which will be routinely used to measure positions of electrons, and measure electron positions BPM_{704e0} .

Apparently, the ion and electron beam trajectories coincide when $BPM_{9e0}=BPM_{9i0}$. Then, the optimal (absolute zero) electron beam position measured with 704 MHz filter is:

$$BPM_{704e} = BPM_{704e0} + (BPM_{9i0}-BPM_{9e0})$$

3. Electron beam motion in solenoid field

Each CS solenoidal module [2] consists of the main solenoid and two weak correcting anti-solenoids (bucking coils), which reduce the longitudinal “tails” of the field. The field profile of solenoids was modelled [3] and measured for each module [4]. The measured field profiles repeat the profile predicted by the model. Figure 3 show the modelled field profile for maximum solenoid current. In our simulations we use this field profile.

Figure 3: Simulated field of the CS solenoidal module.

To simulate motion of the e-beam centroid in magnetic field we use an approach suggested in [5]. Introducing $\xi = x + iy$, $\theta = \theta_x + i\theta_y$ and $B_{\perp} = B_x + iB_y$ we can write equation of motion in a paraxial approximation as:

$$\begin{cases} \xi' = \theta \\ \theta' = \frac{i}{B\rho} (B_{\perp} - B_z \theta) \end{cases} \quad (1)$$

Here a prime defines differentiation with respect to longitudinal coordinate z .

In absence of additional transverse fields ($B_{\perp}$) the off axis field is due to the non-uniformity of B_z only and from Maxwell equations:

$$B_{\perp} = -\frac{\xi}{2} \frac{dB_z}{dz} \quad (2)$$

For the stable numerical solution Eq. (1) must be solved with an implicit method, which gives:

$$\begin{cases} \xi^{n+1} = \xi^n + \frac{\Delta z}{2} (\theta^n + \theta^{n+1}) \\ \theta^{n+1} = \frac{\theta^n + i \frac{\Delta z}{2B\rho} (B_{\perp}^n + B_{\perp}^{n+1} - B_z^n \theta^n)}{1 + i \frac{\Delta z}{2B\rho} B_z^{n+1}} \end{cases} \quad (3)$$

In this paper we use (3) to simulate beam motion through the solenoid module. For the transverse fields at each step of simulation we always use a sum of trajectory correctors' fields and the fields defined by (2).

4. Requirements to beam based alignment of CS solenoids

As it was mentioned in Section 1 the overall RMS angles of the electrons shall be below 100 urad.

In this paper we will consider the case of 1.6 MeV electron beam. For such beam, for its nominal bunch charge of 100 pC, the CS solenoid strength of ~ 70 G is required. We might require electron bunches of higher charge and therefore require the stronger solenoids. Apparently, since the highest peak field of solenoids is ~ 200 G, the limit on acceptable mechanical displacements of the CS solenoid calculated for such field will be a reasonable overestimate (with some safety factor) of the tolerance of solenoid alignment.

Simulating beam motion through the field shown in Fig. 3 according to Eq. 3 we find that the electron beam trajectory will acquire 100 urad angle from solenoid inclination of 0.5 mrad or from solenoid displacement of 0.5 mm.

Therefore, the CS solenoid inclination with respect to the design beam trajectory must be measured and corrected with accuracy much better than 0.5 mrad. The displacement of the CS solenoid magnetic center with respect to the design beam trajectory must be measured and corrected with accuracy much better than 0.5 mm.

5. Hard-edge approximation

The proper hard-edge approximation of the measured real field shall provide both the proper beam focusing and x-y rotation. That is, the hard-edge solenoid field (B) and length (L) shall satisfy the following relations:

$$B = \frac{\int B(z)^2 dz}{\int B(z) dz} \quad (4)$$

$$L = \frac{(\int B(z) dz)^2}{\int B(z)^2 dz}$$

Using (4) we get $L=18.906$ cm and $B = 0.70743 \cdot \max(B(z))$. Figure 4 shows hard edge approximation of the measured solenoidal field.

Figure 4: Measured (orange) and hard-edge approximation (pink) field of the CS solenoidal module.

To check the obtained approximation we compare results of simulations (3) to the beam trajectory found from a standard solenoid transfer matrix:

$$M_{sol} = \begin{pmatrix} \frac{1+c}{2} & \frac{c}{k} & \frac{s}{2} & \frac{1-c}{k} \\ -\frac{ks}{4} & \frac{1+c}{2} & -k\frac{1-c}{4} & \frac{s}{2} \\ -\frac{s}{2} & -\frac{1-c}{k} & \frac{1+c}{2} & \frac{s}{k} \\ k\frac{1-c}{4} & -\frac{s}{2} & -\frac{ks}{4} & \frac{1+c}{2} \end{pmatrix}, \quad s \equiv \sin kL, \quad c \equiv \cos kL, \quad k = \frac{B}{B\rho}, \quad (5)$$

We find a perfect agreement between the beam trajectory in the hard-edge model and in the real distribution of the solenoid field (see Fig. 5).

6. Effect of solenoid shift

If the solenoid magnetic center is shifted from the ideal e-beam trajectory by d_x and d_y , then beam trajectory at the exit of the solenoid is given by:

$$\begin{pmatrix} x_{shift} \\ \theta x_{shift} \\ y_{shift} \\ \theta y_{shift} \end{pmatrix} = M_{sol} \begin{pmatrix} d_x \\ 0 \\ d_y \\ 0 \end{pmatrix} - \begin{pmatrix} d_x \\ 0 \\ d_y \\ 0 \end{pmatrix} \quad (6)$$

Figure 5: An example of the BPM readings simulated (red crosses) according to (3) and found in the hard-edge approximation (blue line). The BPM is located at 3 m from solenoid center. Beam trajectory at the entrance to the solenoid field region has an input angle $\theta_x = -10$ mrad; the beam goes through $x=0$ mm at the center of the solenoid when the solenoid is switched off. $I_{sol}=1$ corresponds to 205.7 G peak field of the solenoid.

The readings of the BPM located at distance z from the solenoid exit are given by:

$$\begin{cases} x_{shiftBPM} = x_{shift} + z \cdot \theta x_{shift} \\ y_{shiftBPM} = y_{shift} + z \cdot \theta y_{shift} \end{cases} \quad (7)$$

As Fig. 6 demonstrates results of Eq. (7) are in perfect agreement with simulations (3).

Figure 6: The BPM readings simulated (red crosses) according to (3) and found from (7) (blue line). The BPM is located at 3.2 m from the solenoid center. The solenoid is shifted by $d_x = 2$ mm and $d_y = -3$ mm. $I_{sol} = 1$ corresponds to 205.7 G peak field of the solenoid.

7. Effect of solenoid inclination

The simplest way to model the effect of an inclined solenoid on the e-beam trajectory is to switch into the inclined reference frame at solenoid entrance and switch back to the normal reference frame at solenoid exit. Then, in the hard-edge approximation the effect is given by:

$$\begin{pmatrix} x_{incl} \\ \theta x_{incl} \\ y_{incl} \\ \theta y_{incl} \end{pmatrix} = M_{sol} \begin{pmatrix} -L\alpha_x/2 \\ \alpha_x \\ -L\alpha_y/2 \\ \alpha_y \end{pmatrix} - \begin{pmatrix} L\alpha_x/2 \\ \alpha_x \\ L\alpha_y/2 \\ \alpha_y \end{pmatrix} \quad (8)$$

The respective readings of the BPM located at distance z from the solenoid exit are given by:

$$\begin{cases} x_{inclBPM} = x_{incl} + z \cdot \theta x_{incl} \\ y_{inclBPM} = y_{incl} + z \cdot \theta y_{incl} \end{cases} \quad (9)$$

Comparison of (9) to the simulations (3) show (see Fig. 7 for an example) the perfect agreement between analytic formulas (8)-(9) and the numerical simulation of beam motion through the real field of the CS solenoidal module.

Figure 7: The BPM readings simulated (red crosses) according to (3) and found from (9) (blue line). The BPM is located at 3.2 m from the solenoid center. The solenoid is inclined by $\alpha_x = 1$ mrad and $\alpha_y = 1.5$ mrad. $I_{sol} = 1$ corresponds to 205.7 G peak field of the solenoid.

8. Effect of trajectory correctors

Each cooling section solenoid is combined with transverse correctors. According to the procedure outlined in Section 1 these correctors will be set to compensate the effect of the residual earth field. In the model suggested in [1] these correctors will be providing 0.17 mrad bending angle. Due to the x-y rotation in solenoidal field there will be an additional effect of transverse correctors on beam trajectory for the turned on solenoid. While this effect is not too large (about 60 urad) we will take it into account nonetheless.

In these studies we assume that longitudinal distribution of the correctors' field repeats the field distribution of the solenoidal module.

Solving (1) in a hard-edge approximation and multiplying the obtained $xx'yy'$ vector by a standard solenoid exit matrix we obtain the following formula for effect of transverse correctors in solenoidal field on the beam trajectory at solenoid exit:

$$\begin{pmatrix} x_{corr} \\ \theta x_{corr} \\ y_{corr} \\ \theta y_{corr} \end{pmatrix} = \begin{pmatrix} \frac{B_y(c-1) + B_x(kL-s)}{Bk} \\ \frac{B_x(1-c) - B_y(s+kL)}{2B} \\ \frac{B_x(1-c) + B_y(kL-s)}{Bk} \\ \frac{B_y(1-c) + B_x(s+kL)}{2B} \end{pmatrix} - \begin{pmatrix} -\frac{B_y L^2}{2B\rho} \\ -\frac{B_y L}{B\rho} \\ \frac{B_x L^2}{2B\rho} \\ \frac{B_x L}{B\rho} \end{pmatrix} \quad (10)$$

The respective readings of the BPM located at distance z from the solenoid exit are given by:

$$\begin{cases} x_{corrBPM} = x_{corr} + z \cdot \theta x_{corr} \\ y_{corrBPM} = y_{corr} + z \cdot \theta y_{corr} \end{cases} \quad (11)$$

Comparisons of (11) to the simulations (3) show (see Fig. 8) good agreement between analytic formulas and the numerical simulations.

It is also worth mentioning that in the model suggested in [1] the beam will be entering the CS solenoid with a small angle of about 20 urad. The effect from this angle on beam-based alignment procedure is negligibly small.

In Section 10 we will include these small angles into our numerical model but we will not account for the effect from these angles in the fitting functions.

9. Additional considerations

Let us expand the sum of the effects of solenoid shift and inclination:

$$\begin{aligned}
x_{shiftBPM} + x_{inclBPM} &= \frac{BL}{B\rho} \left[\frac{d_y}{2} + \frac{\alpha_y}{2} \left(z + \frac{L}{2} \right) \right] - \left(\frac{BL}{B\rho} \right)^2 \left[\frac{d_x}{4} \left(1 + \frac{z}{L} \right) + \frac{\alpha_x}{8} \left(z + \frac{L}{3} \right) \right] + \\
&\quad + \left(\frac{BL}{B\rho} \right)^3 \left[\frac{\alpha_y}{16} z - \frac{d_y}{4} \left(\frac{1}{3} + \frac{z}{2L} \right) \right] \\
y_{shiftBPM} + y_{inclBPM} &= -\frac{BL}{B\rho} \left[\frac{d_x}{2} + \frac{\alpha_x}{2} \left(z + \frac{L}{2} \right) \right] - \left(\frac{BL}{B\rho} \right)^2 \left[\frac{d_y}{4} \left(1 + \frac{z}{L} \right) + \frac{\alpha_y}{8} \left(z + \frac{L}{3} \right) \right] + \\
&\quad + \left(\frac{BL}{B\rho} \right)^3 \left[\frac{d_x}{4} \left(\frac{1}{3} + \frac{z}{2L} \right) - \frac{\alpha_x}{16} z \right]
\end{aligned} \tag{12}$$

Figure 8: The BPM readings simulated (red crosses) according to (3) and found from (11) (blue line). The BPM is located at 3.2 m from the solenoid center. Both transverse correctors inside the solenoid are set to provide 0.17 mrad angle. $I_{sol} = 1$ corresponds to 205.7 G peak field of the solenoid.

Equation (12) shows that the effect of the shift of a solenoid just upstream of the BPM on this BPM readings can be indistinguishable from the effect of the inclination of the solenoid located at some distance upstream of the BPM.

Indeed, Fig. 9 demonstrates that if all CS solenoids are turned on together then from BPM readings it would be hard to determine whether the far-away solenoid is inclined or the nearby one is shifted.

Therefore, it is critical for proper alignment of the e-beam trajectory through the cooling section to be able to have an individual control of each CS solenoid.

Figure 9: Effects of the solenoid (20 cm upstream of the BPM) shifted by 5 mm (left plots) and of the solenoid (3.2 m upstream of the BPM) inclined by 1.5 mrad (right plots).

10. Solenoid beam-based alignment

To find the inclination and the shift of each CS solenoid we will measure dependence of the readings of the downstream BPM on the solenoid current and fit obtained dependence with the following fitting functions:

$$\begin{cases} x_{BPM}(d_x, d_y, \alpha_x, \alpha_y, B) = x_{shiftBPM}(d_x, d_y, B) + x_{inclBPM}(\alpha_x, \alpha_y, B) + x_{corrBPM}(B) \\ y_{BPM}(d_x, d_y, \alpha_x, \alpha_y, B) = y_{shiftBPM}(d_x, d_y, B) + y_{inclBPM}(\alpha_x, \alpha_y, B) + y_{corrBPM}(B) \end{cases} \quad (13)$$

The fit will be obtained by minimizing:

$$\chi^2 = \frac{1}{N-4} \sum_{n=1}^N \left\{ \left[\frac{x_n - x_{BPM}(d_x, d_y, \alpha_x, \alpha_y, B_n)}{\sigma_x} \right]^2 + \left[\frac{y_n - y_{BPM}(d_x, d_y, \alpha_x, \alpha_y, B_n)}{\sigma_y} \right]^2 \right\} \quad (14)$$

Here x_n and y_n are BPM readings corresponding to B_n , and σ_x and σ_y are RMS spread of BPM readings.

We modeled the outlined beam-based alignment process. We used (3) to simulate x_n and y_n . We assumed 10 μm for both σ_x and σ_y . We chose $N=21$.

As a result, even if we use just one BPM (at 3.2 m from solenoid center in our model) for the fitting, the solenoid shift can be found with $\sim 90 \mu\text{m}$ accuracy and solenoid inclination can be found with an accuracy of about 70 μrad .

We can improve this result by using two BPMs for fitting – one at 3.2 m downstream of solenoid center and one at 6.2 m downstream of the solenoid. In that case we obtain the solenoid shift with 40 μm accuracy and solenoid inclination with 30 μrad accuracy. Figure 10 shows an example of the fitting performed with two BPMs.

Figure 10: Fitting (green curve) BPM readings (blue crosses) with two BPMs. First BPM (left plots) is located at 3.2 m downstream of the solenoid center and second BPM (right plot) is located at 6.2 m downstream of the solenoid. In this example $d_x = 5 \text{ mm}$, $d_y = -2 \text{ mm}$, $\alpha_x = 1.5 \text{ mrad}$, $\alpha_y = -3 \text{ mrad}$. $I_{\text{sol}} = 1$ corresponds to 205.7 G peak field of the solenoid.

11. Conclusion

We considered the steps required to align the electron beam trajectory through the LEReC cooling section.

We devised a detailed procedure for the beam-based alignment of the cooling section solenoids.

We showed that it is critical to have an individual control of each CS solenoid current.

Finally, we modeled the alignment procedure and showed that with two BPM fitting the solenoid shift can be measured with 40 μm accuracy and the solenoid inclination can be measured with 30 μrad accuracy. These accuracies are well within the tolerances of the cooling section solenoid alignment.
